Short title: DF-MITO-Porter, an innovative DDS for mitochondria
Mitochondrial dysfunction is associated with a variety of human diseases including inherited mitochondrial diseases, neurodegenerative disorders, diabetes mellitus and cancer. Effective medical therapies for mitochondrial diseases will ultimately require an optimal drug delivery system, which will likely be achieved through innovations in the nanotechnology of intracellular trafficking. To achieve efficient mitochondrial drug delivery, two independent processes, i.e., “cytoplasmic delivery through the cell membrane” and “mitochondrial delivery through the mitochondrial membrane” are required. In previous studies, we developed an octaarginine (R8) modified nano-carrier for efficient cytoplasmic delivery, showing that R8-modified liposomes were internalized into cells efficiently. On the other hand, we also constructed MITO-Porter for the mitochondrial delivery of macromolecules, a liposome-based carrier that delivers cargos to mitochondria via membrane fusion. Here, we report the development of a Dual Function MITO-Porter (DF-MITO-Porter), based on the concept of integrating both R8-modified liposomes and MITO-Porter. We show that the DF-MITO-Porter effectively delivers exogenous macro-biomolecules into the mitochondrial matrix, and provide a demonstration of its potential use in therapies aimed at mitochondrial DNA.
INTRODUCTION

Mitochondrial dysfunction is implicated in a variety of human diseases including mitochondrial inherited diseases, neurodegenerative disorders, diabetes mellitus and cancer. Effective medical therapies for such diseases will ultimately require an optimal drug delivery system, which will likely be achieved through innovations in the nanotechnology of intracellular trafficking. In addition, the use of therapeutic agents will be needed to overcome the impregnable mitochondrial membrane to exert pharmacological effects inside mitochondria. Previous studies reported that the conjugation of mitochondrial targeting signal peptides to exogenous proteins and small linear DNAs enhanced their delivery to mitochondria, but this strategy failed, in cases of macromolecules and hydrophobic molecules, including mitochondrial DNA and proteins.

To achieve efficient mitochondrial drug delivery, two independent processes i.e., “cytoplasmic delivery through the cell membrane” and “mitochondrial delivery through the mitochondrial membrane” are required. In previous studies, we reported on the development of an octaarginine (R8) modified nano-carrier for efficient cytoplasmic delivery and a MITO-Porter for the mitochondrial delivery of macromolecules. The former, R8 is a synthetic peptide that mimics the trans-activating transcriptional activator (TAT) derived from the human immunodeficiency virus. We showed that high-density R8-modified liposomes were internalized primarily via macropinocytosis and are efficiently delivered to the cytosol, similar to an adenovirus vector. On the other hand, we proposed a MITO-Porter, which is different from mitochondrial targeting signal peptide system, for mitochondrial delivery. The MITO-Porter is a liposome-based nano-carrier that delivers cargos to mitochondria via membrane fusion. Using the green fluorescence protein as a model macromolecule and analysis by confocal laser scanning microscopy (CLSM), we were able to confirm mitochondrial macromolecule delivery by the MITO-Porter. We were also able to verify that the MITO-Porter delivered cargoes to the mitochondrial matrix, which pools mitochondrial DNA (mtDNA), using this novel imaging method.
A nano-carrier system which achieves both efficient cytoplasmic delivery and mitochondrial macromolecule delivery could open new avenues for mitochondrial disease therapies. We report herein on the development of a Dual Function MITO-Porter (DF-MITO-Porter), which has the potential for serving as a nano-device for mitochondrial disease therapies, based on the concept integrating both high-density R8-modified liposomes and the conventional MITO-Porter (Fig. 1). The critical structural elements of the DF-MITO-Porter include a complexed particle of cargos that are coated with two mitochondria-fusogenic inner membranes and two endosome-fusogenic outer membranes. Modification of the outer envelope-surface with a high density of R8\textsuperscript{18,19} greatly assists in the efficient internalization of the carriers into cells (1st step). Inside the cell, the carrier escapes from the endosome into the cytosol via membrane fusion, a process that is mediated by the outer endosome-fusogenic lipid membranes (2nd step). The carrier then binds to mitochondria via R8 (3rd step) and fuses with the mitochondrial membrane (4th step). Recent studies reported that TAT has the ability to deliver a certain cargo to mitochondria,\textsuperscript{23,24} and we also showed that modification of the liposome-surface with R8 significantly enhances binding to mitochondria, regardless of the lipid composition.\textsuperscript{6} Thus, we chose R8, not only as a cytoplasmic delivery device but as a mitochondrial targeting device as well.

In this study, we attempted to prepare DF-MITO-Porter with mitochondria-fusogenic inner membranes and endosome-fusogenic outer membranes, and optimize the characteristics. Intracellular observation using CLSM permitted us to compare mitochondrial targeting activity between DF-MITO-Porter and conventional MITO-Porter. Moreover, we validated that DF-MITO-Porter delivered exogenous macro-biomolecules into mitochondria matrix. Finally, we screened the optimal lipid composition for the DF-MITO-Porter, for achieving a high mitochondrial membrane fusion activity and low cytotoxicity.

RESULTS
Construction of DF-MITO-Porter

The findings reported herein, confirm that the DF-MITO-Porter has the ability to deliver macromolecules into the mitochondrial matrix, which pools mtDNA, over the mitochondrial double-membrane structure. DNase I protein was chosen as a model macromolecule, which permitted us to estimate mitochondrial matrix delivery of the carrier. It was expected that mtDNA would be digested, when the mitochondrial matrix delivery of DNase I progressed. The construction of the DF-MITO-Porter encapsulating DNase I requires the following three steps (Fig. 2a): (1) the construction of nano particles containing DNase I; (2) coating the nano particles with mitochondria-fusogenic envelope; (3) further coating endosome-fusogenic envelope in a step-wise manner, based on our previous report regarding gene packaging with two-different types of lipid layers.25

We first determined the optimal conditions for complexation between DNase I protein (M.W. 36 kDa, weak negative charge) and stearyl R8 (STR-R8)26 that would be suitable for the complexation of proteins.27 We mixed DNase I with STR-R8 at several complex-inducer/protein (C/P) molar ratios to form nano-particles and then determined their diameters and ζ-potentials (surface charges) (Figs. 2b,c). Figure 2b shows data for the diameters of the complexes. Particles with diameters of less than 200 nm were formed at C/P molar ratios higher than 10. Figure 2c shows the ζ potentials for the complexes. The charges of the particles were changed from minus to plus with increasing C/P ratios. In this study, we chose small positively charged particles formed at a C/P molar ratio of 10 for preparation of the DF-MITO-Porter. We also prepared small unilamellar vesicles (SUVs) with various lipid compositions (Table S1). The positively charged particles were then coated with the first two-layered envelope by the assembly of negatively charged SUVs. The resulting structure was modified with STR-R8 to reverse the surface charge, and then coated with the second envelope via the fusion of negatively charged SUVs. Finally, the carrier-surface was modified with STR-R8 to give the final DF-MITO-Porter, which is a tetra-lamellar structured nano particle. The physiochemical properties of the intermediate particles are summarized in Table 1.
The size, polydispersity index (PDI) as an indicator of the particle-size distribution, and the ζ potential of the DF-MITO-Porter and control carrier are summarized in Fig 2d. The outer envelope of all carriers had an endosome-fusogenic composition [DOPE/PA/STR-R8 (7:2:1, molar ratio)]. For the DF-MITO-Porter, inner envelope had a mitochondria-fusogenic composition [DOPE/SM/CHEMS/STR-R8 (9:2:1:1, molar ratio) or DOPE/PA/STR-R8 (9:2:1, molar ratio)], while a non-mitochondrial fusogenic composition [EPC/CHEMS/STR-R8 (9:2:1, molar ratio)] was used in the control inner envelope. As shown in Fig 2d, the prepared carriers were positively charged nano particles with a homogeneous structure. We also prepared a conventional MITO-Porter for purposes of checking the multi-layered structure value (Figure S1).

Intracellular observation of DF-MITO-Porter using confocal laser scanning microscopy and evaluation for mitochondrial targeting activity

We observed the intracellular trafficking of the DF-MITO-Porter and the conventional MITO-Porter using CLSM to validate that the carrier was able to regulate its intracellular trafficking for efficient mitochondrial delivery. In the case of the DF-MITO-Porter, many yellow clusters were observed (Fig. 3a), indicating that the NBD-DOPE in the carriers (green) are co-localized with mitochondria (stained red with MitoFluor Red 589). Moreover, it was confirmed that the DF-MITO-Porter accumulated in mitochondria more efficiently compared to the conventional MITO-Porter (Fig. 3). We next evaluated the fraction of mitochondrial targeted positive cells based on images observed by CLSM (see MATERIALS AND METHODS for details). The fraction of mitochondrial targeted positive cells of the total number of observed cells was calculated as follows;

\[
\text{Fraction of mitochondrial targeted positive cells (\%) = } \frac{N_{mt}}{N_{tot}} \times 100
\]

where \(N_{mt}\) and \(N_{tot}\) represent the number of mitochondrial targeted positive cells and the total number of cells observed, respectively.
Figs. 4a,b show Z-series images of the intracellular observation of the DF-MITO-Porter and the conventional MITO-Porter, respectively. The yellow pixel areas where carriers (green) are co-localized with mitochondria (red) were marked in each xy plane. We defined cells where carriers were co-localized with mitochondria in at least one Z-series image as mitochondrial targeted positive cells. Consequently, the fraction of mitochondrial targeted positive cells of the DF-MITO-Porter (more than 80 %) was considerably higher than the corresponding value for the conventional MITO-Porter (Fig. 4c). This suggests that a multi-layered structure can be very useful for mitochondrial delivery in living cells.

Relationship between mitochondrial membrane fusion activity and cytotoxicity

The possibility that the DF-MITO-Porter might induce cytotoxicity cannot be excluded, since this system fuses with the mitochondria, which play a role in the homeostasis of vital physiological functions. Therefore, we investigated the relationship between mitochondrial membrane fusion activity and cytotoxicity. In this experiment, we prepared an empty DF-MITO-Porter with various inner mitochondria-fusogenic envelopes as previously reported,17 and then evaluated their cell viabilities. The graph in Fig. 5 shows the relationship between mitochondrial membrane fusion activity (x-axis) and cell viability (y-axis). We also calculated Pearson’s correlation coefficient (r = 0.21), and determined if the correlation coefficient was significantly different from zero using a t-test (p > 0.05). We did not find a significant correlation between mitochondrial membrane fusogenic activity and cell viability. These results suggest that a high fusogenic activity with the mitochondrial membrane induces cytotoxicity is not universally true. The finding that a carrier with an inner envelope composed of SM was optimal for the DF-MITO-Porter is particularly noteworthy, since it has a high mitochondrial membrane fusogenic activity but low cytotoxicity.
Evaluation of mtDNA-levels after the mitochondrial delivery of DNase I using the DF-MITO-Porter

To validate the conclusion that the DF-MITO-Porter is useful as a carrier of therapeutic cargos, we examined the delivery of DNase I protein to the mitochondrial matrix, since the latter is an active bio-molecule that functions inside mitochondria. In a previous study, we reported on the successful mitochondrial matrix delivery of the MITO-Porter, as evidenced by the use of our novel imaging method. In the paper, we used propidium iodide (PI), a membrane-impermeable red-fluorescent dye for staining nucleic acids as an aqueous phase marker for the MITO-Porter. This dye permits mitochondrial matrix delivery to be confirmed, by the detection of red-fluorescent light, because the light is emitted as the result of the conjugation of the dye with mtDNA in the mitochondrial matrix. We first confirmed mitochondrial matrix delivery in isolated rat liver mitochondria using the MITO-Porter. CLSM analyses showed that this system can be used to efficiently visualize mtDNA, not only in isolated mitochondria, but in living cells as well. We also verified that no red-fluorescent light was produced when PI only was incubated with isolated mitochondria or living cells, indicating that PI did not gain access to mtDNA inside mitochondrial matrix. Finally, the fact that the red fluorescence could be detected in living cells in spectral imaging fluorescent microscopy experiments clearly demonstrated that the MITO-Porter successfully delivered its cargo to the mitochondrial matrix. Based on our previous report, we conclude that the DF-MITO-Porter has the ability to deliver cargoes to the mitochondrial matrix.

To verify that mtDNA-levels were decreased after the mitochondrial delivery of DNase I using the DF-MITO-Porter, we evaluated mtDNA-levels within cells using PCR. DNase I protein encapsulated in carriers were incubated with HeLa cells. The cellular DNA was then purified and subjected to the PCR. PCR assays to detect the ND6 and β-Actin genes were performed in order to detect both mtDNA and nuclear DNA. The primers used in these experiments are summarized in Table S2. Figure 6 shows agarose gel electrophoresis data for the PCR products derived from mtDNA (Fig.
6a) and nuclear DNA (Fig. 6b). In the case of the DF-MITO-Porter, decreases in mtDNA-levels were observed (lanes 4, 5 in Fig. 6a), whereas carriers with a low mitochondrial fusion activity had a negligible effect on mtDNA-levels (lane 3 in Fig. 6a). This result suggests that DNase I is delivered to mitochondria by the DF-MITO-Porter, as indicated by the digestion of mtDNA by DNase I to some extent. On the other hand, a decrease in nuclear DNA-levels was not detected in any of the carriers (Fig. 6b). Moreover, we quantified mtDNA-levels within the cells using real-time PCR (Fig. 6c). The results showed that the DF-MITO-Porter decreased mtDNA-levels compared with carriers with a low mitochondrial fusion activity. We also confirmed that the MITO-Porter has a high fusogenic activity for mitochondria, but that is failed to effectively fuse with the nucleus (data not shown). Based on these results, it is presumed that the mitochondrial specific fusion activity of the MITO-Porter might be involved in a pathway related to the selective digestion of mtDNA.

DISCUSSION

In this study, we attempted to achieve macromolecule packaging using a multifunctional envelope-type nano-device (MEND) preparation technique. The MEND consists of a condensed pDNA core and a lipid envelope equipped with various functional devices that mimic envelope-type viruses29,30. The condensation of pDNA into a compact core prior to its inclusion in the lipid envelope has several advantages as follows: protection of pDNA from DNase; size control; and, improved packaging efficiency resulting from electrostatic interactions between the condensed core and the lipid envelope. To date, we have been successful in efficiently packaging not only pDNA, but also oligo nucleic acids, proteins and other substances into a MEND27,31-33. On the other hand, the MITO-Porter system delivers cargos into mitochondria via a membrane fusion mechanism. Therefore, large cargoes could be delivered to mitochondria, provided that the cargoes can be encapsulated in the MITO-Porter. Accordingly, a combination of a MITO-Porter and a macromolecule packaging technique in MEND
preparations would likely achieve the mitochondrial delivery of macromolecules such as pDNA, mtDNA, oligo nucleic acids and proteins.

We constructed the DF-MITO-Porter according to Fig. 2a, using the multi-layering method. First, a di-lamellar structured nano particle (D-SNP) was prepared through membrane fusion of neighboring SUVs, triggered by the assembly of negatively charged SUVs around the positively charged complexed nano-particle of DNase I protein. As previously proposed, it is possible that core particles can form a di-lamellar structure during liposome incubation. The surface of the resulting particles is then modified with STR-R8 to reverse the surface charge. Next, R8-modified D-SNP was coated with the second envelope, again through the fusion of negatively charged SUV to produce T-SNP. If the 2nd SUVs (~60 nm) only bind to the D-SNP (~140 nm), the mean diameter would be expected to be approximately 260 nm. However, the resulting particle had a diameter of ~150 nm, suggesting that the 2nd SUVs fuse with each other, forming a T-SNP. The conversion of ζ potential in each coating process strongly suggests that the complexed nano-particles of DNase I protein underwent a step-wise encapsulation. Thus, the resulting DF-MITO-Porter consists of two types of lipid layers. Table 1 shows physicochemical properties of intermediate of DF-MITO-Porter.

We applied the confocal image-assisted three-dimensionally integrated quantification (CIDIQ) method to evaluate the fraction of mitochondrial targeted positive cells and counted number of mitochondrial targeted positive cells (see MATERIALS AND METHODS for details). Z-series images of the cells after transduction were observed by the LSM510 as shown in Figs. 4a,b, and the total brightness of each region of interest was then quantified by the CIDIQ method. The yellow pixel areas where carriers (green) co-localized with mitochondria (red) were marked in each xy plane. Mitochondrial targeted positive cells were defined as cells where carriers were co-localized with mitochondria in at least one Z-series image, and have a significant effect on the fraction of mitochondrial targeted positive cells (%). As shown in Fig. 4c, the fraction of mitochondrial targeted positive cells produced using the DF-MITO-Porter (more than 80%) was considerably higher than that for the conventional MITO-Porter (about 25%). This result indicates that the DF-MITO-Porter was 3-
fold more efficient than a conventional MITO-Porter in numbers of mitochondrial targeted positive cells, suggesting that a multi-layered structure can be very useful for improving mitochondrial delivery.

Mitochondrial delivery requires the regulation of many intracellular trafficking steps. In this study, we attempted to improve endosomal escape using a multi-layered structure with endosomal fusogenic activity. As a result, the DF-MITO-Porter could deliver molecules to mitochondria more efficiently than a conventional carrier. However, it would be difficult to achieve selective mitochondrial delivery using the current DF-MITO-Porter. On the other hand, the conjugation of mitochondrial targeting signal peptides can achieve selective mitochondrial delivery,\textsuperscript{10,11} but this strategy fails, in cases of macromolecules and hydrophobic molecules.\textsuperscript{12-14} In the future, we plan to integrate mitochondrial targeting signal peptides and a MITO-Porter system to achieve the selective delivery of macromolecules to mitochondria. Studies concerning this are currently in progress.

The DF-MITO-Porter developed in this study, is an innovative nano-device for mitochondrial delivery, which has the ability to pass through endosomal and mitochondrial membranes via step-wise membrane fusion. The findings show that the DF-MITO-Porter delivers exogenous macro-biomolecules into the mitochondrial matrix. Moreover, we identified the optimal lipid composition for the DF-MITO-Porter, for achieving a high mitochondrial membrane fusion activity and low cytotoxicity. Our ultimate goal is to develop a mitochondrial drug delivery system, not only effective cargo delivery, but also a system that will be functional inside a mitochondrion for therapy. Future studies will involve attempts to improve the DF-MITO-Porter in terms of mitochondrial gene function with experts in the field of mitochondrial molecular biology. Studies directed toward this goal are currently in progress.

MATERIALS AND METHODS

Materials
Cholesterol (Chol), 1,2-dioleoyl-sn-glycero-3-phosphatidyl ethanolamine (DOPE), 7-nitrobenz-2-oxa-1, 3-diazole labelled DOPE (NBD-DOPE), and rhodamine-DOPE were purchased from Avanti Polar lipids (Alabaster, AL). Egg yolk phosphatidyl choline (EPC) was obtained from Nippon Oil and Fats Co. (Tokyo, Japan). Cholesteryl hemisuccinate (5-cholesten-3-ol 3-hemisuccinate; CHEMS), cardiolipin (CL), phosphatidic acid (PA), phosphatidyl glycerol (PG), phosphatidyl inositol (PI), phosphatidyl serine (PS), and sphingomyelin (SM) were purchased from Sigma (St. Louis, MO). Stearyl octaarginine (STR-R8)\(^{26}\) was obtained from KURABO INDUSTRIES LTD (Osaka, Japan). DNase I protein (from bovine pancreas, Grade II) was purchased from Roche Diagnostics GmbH (Mannheim Germany). HeLa human cervix carcinoma cells were obtained from RIKEN Cell Bank (Tsukuba, Japan). Dulbecco’s modified Eagle medium (DMEM) and fetal bovine serum (FBS) were purchased from Invitrogen Corp. (Carlsbad, CA). All other chemicals used were commercially available reagent-grade products.

**Preparation of complexed protein particles with STR-R8**

DNase I protein was gently mixed with the STR-R8, as complex-inducer, in 100 \(\mu\)l of 10 mM HEPES buffer (HB, pH 7.4), followed by incubation for 15 min at 25ºC to form complexed protein particles. Particles of the DNase I/STR-R8 were formed using 50 \(\mu\)g of DNase I and STR-R8 in a series of molar ratios of complex-inducer/protein (C/P).

**Construction of DF-MITO-Porter**

The DNase I-encapsulated Dual Function MITO-Porter (DF-MITO-Porter) was constructed by the multi-layering method (Fig. 2a), as previously reported.\(^{25}\) A solution of DNase I protein in HB (1 mg/ml) was mixed with an STR-R8 solution to form complexed protein particles by gently pipetting at a
C/P molar ratio of 10, followed by incubation for 15 min at 25ºC. For inner and outer envelopes, various SUVs were prepared. The suspended negatively charged SUVs and complexed protein particles were mixed at a ratio of 3 : 1 (v/v) to coat the complexed protein particles with a double-lipid envelope to produce a di-lamellar structured nano particle (D-SNP). These SUVs composed of mitochondria-fusogenic lipid [DOPE/PA = 9 : 2, DOPE/SM/CHEMS = 9 : 2 : 1 (molar ratio)] or non-fusogenic lipid [EPC/CHEMS = 9 : 2 (molar ratio)]. An STR-R8 solution (10 mol% of total lipid) was added to the suspension of D-SNPs to reverse the surface charge. This suspension was then mixed with endosome-fusogenic SUV [DOPE/PA = 7 : 2 (molar ratio)] at a ratio of 1 : 2 (v/v) to generate particles with a double endosome-fusogenic envelope, hereafter referred to a tetra-lamellar structured nano particle (T-SNP). The STR-R8 solution (10 mol% of endosome-fusogenic lipid) was added to the suspension of T-SNP to modify the outer envelope with R8. We refer to the R8 modified T-SNP with mitochondria-fusogenic inner envelope that contain PA and SM as the DF-MITO-Porter (PA) and the DF-MITO-Porter (SM), respectively.

**Measurement of diameter and ζ potential**

Particle-diameter was measured by a quasi-elastic light scattering method and ζ potentials were determined electrophoretically by means of an electrophoretic light scattering spectrophotometer (Zetasizer Nano ZS; Malvern Instruments, Herrenberg, Germany).

**Intracellular trafficking observation of DF-MITO-Porter using CLSM**

HeLa cells (4 x 10⁴ cells/mL) were cultured in 35 mm dishes (BD Falcon, NJ) with DMEM, which contained 10% FBS, under an atmosphere of 5% CO₂ / air at 37ºC for 24 hr. The cells were washed with serum-free medium before incubation with carriers. The DF-MITO-Porter or conventional
MITO-Porter, labeled with 0.5 mol % NBD-DOPE lipids, were incubated with HeLa cells (final lipid concentration, 13.5 μM) to observe the intracellular trafficking of the carriers themselves. After a 1-hr incubation under an atmosphere of 5% CO₂ / air at 37°C, the cells were washed with serum-free medium, and further incubated in medium with 10% serum for 100 min in the absence of carriers. After incubation, MitoFluor Red 589 (Molecular Probes; Eugene, OR) was applied to the medium at a final concentration of 100 nM to stain the mitochondria. After incubation for 20 min, the cells were washed with serum-free medium and then observed by confocal laser scanning microscopy (CLSM) (LSM510; Carl Zeiss Co. Ltd., Jena, Germany). The cells were excited with 488 nm and 568 nm light from an Ar/Kr laser. A series of images were obtained using an LSM510 microscope with a water immersion objective lens (Achroplan 63x/NA = 0.95) and a dichroic mirror (HFT488/568). The two fluorescence detection channels (Ch) were set to the following filters: Ch1: LP585 (red); Ch 2: BP 505-550 (green).

Fluorescence image processing for calculation of fraction of mitochondrial targeted positive cells

Fluorescent and bright-field images were captured using an LSM510 microscope. Images obtained from the bottom of the coverslip to the top of the cells were recorded by the LSM510 on a PC as shown in Figs. 4a,b. Each 8-bit TIFF image was analyzed using the Image-Pro plus v.4.5.1.26 software (Media Cybernetics, Inc., Bethesda, MD) to quantify the total brightness of each region of interest based on confocal image-assisted three-dimensionally integrated quantification (CIDIQ) method.35,36 The fraction of mitochondrial targeted positive cells was determined as described below. First, the yellow pixel areas where carrier (green) co-localized with mitochondria (red) were marked in each xy plane. We define cells where carriers co-localized with mitochondria in at least one Z-series image as mitochondrial targeted positive cells. In some cases, it was difficult to distinguish the localization of the carrier between on and outside the mitochondria. Therefore, criteria were introduced to classify the carrier cluster as co-localized in the mitochondria when more than 50% of the pixels of
the carrier were mitochondria targeted positive (defined as green fluorescent values larger than 130). The fraction of mitochondrial targeted positive cells was calculated as follows;

\[
\text{Fraction of mitochondrial targeted positive cells (\%) } = \frac{N_{\text{mt}}}{N_{\text{tot}}} \times 100
\]

where \(N_{\text{mt}}, N_{\text{tot}}\) represent the number of mitochondrial targeted positive cells and the total number of cells observed, respectively.

**Investigation of the relationship between mitochondrial membrane fusion activity and cell viability.**

We prepared a graph showing mitochondrial membrane fusion activity (x-axis) and cell viability (y-axis). For the x-axis, we used data reported in a previous study,\(^1\) where we calculated mitochondrial fusion activities in terms of the cancellation of fluorescent resonance energy transfer (**Figure S2**). For the y-axis, we prepared various DF-MITO-Porters unencapsulating DNase I and evaluated their cell viabilities as described below. HeLa cells (1 x 10\(^4\) cells/well) were incubated in a 24 well plate (Corning, NY) with DMEM containing 10% FBS, under 5% CO\(_2\) / air at 37°C for 24 hr. Sample-suspensions in 0.25 mL of serum-free DMEM (containing 12.5 \(\mu\)L of carriers) were added to the cells after washing the cells with phosphate-buffer saline (PBS (-)), followed by incubation under 5% CO\(_2\) at 37°C for 3 hr. After replacing the medium with fresh DMEM containing 10% serum, the cells were incubated for a further 21 hr. The cells were then washed with PBS (-), and cell viability was measured using a Cell Proliferation Assay System with a Tetra Color ONE (SEIKAGAKU BIOBUSINESS CORPORATION, Tokyo, Japan), according to the instructions provided by the manufacturer. Briefly, a tetrazolium (WST-8) was added to a final volume of 275\(\mu\)L /well. After 1 h incubation, absorbance at 450 nm was measured by means of a Benchmark plus microplate reader (Bio-Rad Laboratories, Inc., CA, USA). Cell viability was calculated as follows;
Cell viability (%) = $\frac{A_T}{A_U} \times 100$

where $A_T$, $A_U$ represent the absorbance at 450 nm when cells were treated and untreated with samples, respectively.

**Evaluation for mtDNA-levels after the mitochondrial delivery of DNase I.**

HeLa cells (2 x $10^5$ cells/well) were seeded on a 6-well plate (Corning, NY) with DMEM containing 10% FBS, under 5% CO$_2$ / air at 37°C for 24 hr. Sample-suspensions containing 6 μg of DNase I in 1 mL of serum-free DMEM were added to the cells after washing them with PBS (-), followed by incubation under 5% CO$_2$ at 37°C for 3 hr. After the addition of fresh DMEM containing 10% serum, the cells were incubated for a further 21 hr. The cells were then washed with PBS (-), trypsinized, suspended in DMEM with serum, precipitated by centrifugation (1,800 g, 4°C, 3 min). The pellets were washed with PBS (-) and precipitated by centrifugation (1,800 g, 4°C, 3 min). To evaluate the levels of mtDNA and nuclear DNA, total cellular DNA was purified from cell lysates by means of a GenElute Mammalian Genome DNA Miniprep kit (Sigma–Aldrich, St. Louis, MO, USA) and subjected to the PCR.

The PCR reaction mixture contained, in a total volume of 25 μL, 10 mM of Tris-HCl (pH 8.3), 1.5 mM of MgCl$_2$, 50 mM of KCl, 200 μM of each one of the deoxynucleoside triphosphates, 0.5 μM of primers ND6 (+) and ND6 (-) for mtDNA detection or primers β-Actin (+) and β-Actin (-) for nuclear DNA (as shown in **Table S2**), and 10 ng of DNA obtained from HeLa cell lysates. After the addition of 0.625 U of Taq DNA polymerase (Finnzymes PCR Reagents; Thermo Fisher Scientific, Waltham, MA), the reaction mixture was first incubated at 94°C for 2 min, then subjected to 30 cycles of 30 sec at 94°C, 30 sec at 55°C and 45 sec at 72°C, and finally to 10 min at 72°C. Each 5μL of PCR products were subjected to electrophoresis in 2% agarose gel in TAE (40 mM Tris-HCl, 40 mM acetic acid, 1 mM
EDTA, pH 8.0) at 100 V for 30 min. The DNA bands were visualized by UV after ethidium bromide staining.

For quantitative real-time PCR, each target, ND6 encoded on mtDNA, was amplified on the same plate with the reference, β-Actin, with the SYBR Green Real-time PCR Master Mix (TOYOBO Co., Osaka, Japan) and the 7500 Real Time PCR System (Applied Biosystems Co., Foster City, CA, USA), and the relative mtDNA amounts and range were determined. Briefly, we normalized each set of samples using the difference in threshold cycles (ΔCₜ) between the sample mtDNA and the housekeeping gene (β-Actin): ΔCₜ = (ΔCₜ sample − ΔCₜ β-Actin). The calibrator sample (ΔCₜ calibration) was assigned as the sample with non-treatment cell. Relative mtDNA levels were calculated by the expression 2⁻ΔΔCₜ where ΔΔCₜ = ΔCₜ sample (n) − ΔCₜ calibration (n). Each reaction was done, at least in duplicate. For the real-time PCR, two types of primers ND6 (+) and ND6 (-) and primers β-Actin (+) and β-Actin (-) were used as shown in Table S2.

ACKNOWLEDGMENT.

This work was supported, in part by, a Grant-in-Aid for Young Scientists (B) and Grants-in-Aid for Exploratory Research from the Ministry of Education, Culture, Sports, Science and Technology of Japanese Government (MEXT) and by the Program for Promotion of Fundamental Studies in Health Sciences of the National Institute of Biomedical Innovation, Japan (NIBIO). We also thank Milton Feather for his helpful advice in writing the manuscript.

**Figure 1.** Schematic diagram illustrating mitochondrial macromolecule delivery via a series of membrane fusions using Dual Function (DF)-MITO-Porter. Complexed particles of cargos are coated with mitochondria-fusogenic lipid envelope (inner) and endosome-fusogenic lipid envelope (outer). Octaarginine (R8) functions as a cell-uptake device in the outer envelope and as a mitochondrial targeting device in the inner envelope.

**Figure 2.** Construction of the Dual Function (DF)-MITO-Porter. (a) Schematic diagram of the preparation of the DF-MITO-Porter. SUV, small unilamellar vesicles; D-SNP, di-lammelar structured nano particle; T-SNP, tetra-lamellar structured nano particle. Diameter (b) and ζ potential (c) of nanoparticles of DNase I complexed with stearyl octaarginine (STR-R8) at various molar ratios. Data are represented by the mean ± S.D. (n = 3-7). C/P, complex-inducer (STR-R8) / protein (DNase I). (d) Characteristics of the DF-MITO-Porter containing DNase I. Diameter, polydispersity index (PDI) and ζ potential of carriers were measured. Data are represented by the mean ± S.D. (n = 3-4). DOPE, 1,2-dioleoyl-sn-glycero-3-phosphatidyl ethanolamine; PA, phosphatidic acid; CHEMS, cholesteryl hemisuccinate (5-cholesten-3-ol 3-hemisuccinate); SM, sphingomyelin.

**Figure 3.** Intracellular distribution of carriers was analyzed by confocal laser scanning microscopy. DF-MITO-Porter (SM) (a) and conventional MITO-Porter (SM) (b) labeled with NBD-DOPE (green) were incubated with HeLa cells. Mitochondria were stained with MitoFluor Red 589 (red) prior to observation. The clusters present in the mitochondria (yellow) are indicated. Scale bars, 10 μm.

**Figure 4.** Z-series images of intracellular observation and the fraction of mitochondrial positive targeted cells. DF-MITO-Porter (SM) (a) and the conventional MITO-Porter (SM) (b) labeled with NBD-DOPE were incubated with HeLa cells at 37ºC for 1 hr. After replacing the medium with fresh medium, the cells were incubated for a further 1 hr. Mitochondria were stained with MitoFluor Red 589 prior to observation. Fluorescent and bright-field images were captured using confocal laser scanning...
microscopy (LSM510). Images obtained from the bottom of the coverslip to the top of the cells were recorded by the LSM510 on a PC. The clusters present in the mitochondria are indicated as yellow arrows. Scale bar, 50 μm. (c) Mitochondrial targeting activity was calculated from the images shown in Figs. 4a,b, (see MATERIALS AND METHODS for details).

**Figure 5.** Relationship between mitochondrial membrane fusion activity (x-axis) and cell viability (y-axis). For x-axis, we used data reported in our previous study\(^{17}\) (Figure S2). For the y-axis, we calculated cell viability after the addition of carriers without DNase I to HeLa cells. Data are represented by the mean ± S.E. (n = 4-5). CL, cardiolipin; PI, phosphatidyl inositol; PG, phosphatidyl glycerol; PS, phosphatidyl serine; PA, phosphatidic acid; CHEMS, cholesteryl hemisuccinate (5-cholesten-3-ol 3-hemisuccinate); SM, sphingomyelin; Chol, cholesterol.

**Figure 6.** Evaluation of mtDNA-levels after the mitochondrial delivery of DNase I using PCR. DNase I encapsulated in the DF-MITO-Porter (SM), the DF-MITO-Porter (PA) or the control carrier with low mitochondrial fusion activity were incubated with HeLa cells. Cellular DNA was then purified and subjected to the PCR as described in the MATERIALS AND METHODS section. PCR assays for ND6 and β-Actin genes detection were performed in order to detect mtDNA (a) and nuclear DNA (b), respectively. Lane 1, 100 bp DNA Ladder; lane 2, Non-treatment; lane 3, control carrier with low mitochondrial fusion activity [EPC/CHEMS/STR-R8]; lane 4, DF-MITO-Porter (SM); lane 5, DF-MITO-Porter (PA). We also quantified mtDNA-levels within cells using real-time PCR (c). Data are represented as the mean ± S.D. (n = 3-6). *Significant difference between control carrier (EPC/CHEMS/STR-R8) and other carriers (p < 0.05 by one-way ANOVA, followed by Bonferroni correction). ND6, mitochondrial NADH dehydrogenase 6.

**Figure S1.** Construction of the conventional MITO-Porter encapsulating DNase I. The conventional MITO-Porter encapsulating DNase I was constructed in the following three steps. First, 1 mg/ml of DNase I protein dissolved in 10 mM HEPES buffer (HB, pH 7.4) was mixed with an STR-R8 solution to form complexed protein particles by gentle pipetting at a C/P molar ratio of 10, followed by incubation for 15 min at 25°C. The suspension of complexed protein particles was diluted with HB to 0.125 mg/mL of DNase I protein. Then, 0.25 ml of the resulting suspension was added to the lipid film, formed by the evaporation of a chloroform solution of 137.5 nmol lipids on the bottom of a glass tube, followed by incubation for 15 min to hydrate the lipids. The glass tube was sonicated in a bath-type sonicator (85 W; Aiwa Co., Tokyo, Japan) for 15 sec to coat the complexed protein particle with lipids. To attach R8 to the surface of the carrier, a solution of STR-R8 (10 mol% lipids) was added to the resulting suspensions. The envelope of conventional MITO-Porters had the following mitochondria-fusogenic composition: [DOPE/SM/CHEMS/STR-R8 (9:2:1:1, molar ratio) or DOPE/PA/STR-R8 (9:2:1, molar ratio)], while a non-mitochondrial fusogenic composition [EPC/CHEMS/STR-R8 (9:2:1, molar ratio)] was used in the control carrier. DOPE, 1,2-dioleoyl-sn-glycero-3-phosphatidyl ethanolamine; PA, phosphatidic acid; CHEMS, cholesteryl hemisuccinate (5-cholesten-3-ol 3-hemisuccinate); SM, sphingomyelin, PDI, polydispersity index.

**Figure S2.** Summary of mitochondrial membrane fusion activities of R8 modified DOPE-LP. We previously reported that liposomes containing both DOPE and STR-R8 (R8 modified DOPE-LP) were optimal for mitochondrial membrane fusion (Y. Yamada et al., Biochim. Biophys. Acta. 1778: 423-432 (2008)). DOPE, 1,2-dioleoyl-sn-glycero-3-phosphatidyl ethanolamine; CL, cardiolipin; PI, phosphatidylinositol; PG, phosphatidyl glycerol; PS, phosphatidyl serine; PA, phosphatidic acid; CHEMS, cholesteryl hemisuccinate (5-cholesten-3-ol 3-hemisuccinate); SM, sphingomyelin; Chol, cholesterol. Data are represented by the mean ± S.D. (n=3).
Table S1. Lipid composition and property of SUVs.

Small unilamellar vescicles (SUVs) with various lipid compositions were prepared by the following procedure. A 1.5 mL aliquot of 10 mM HEPES buffer (pH 7.4) was applied to 825 nmol of a dried lipid film formed on the bottom of a glass tube. After incubation for 10 min, the suspensions were sonicated for 15 sec using a bath-type sonicator (85 W, Aiwa Co., Tokyo, Japan). The resulting suspensions were then sonicated using a probe-type sonicator (SONIFIER MODEL 250 D, BRANSON, Danbury, CT, USA) for 10 min on ice to form SUV. DOPE, 1,2-dioleoyl-sn-glycero-3-phosphatidyl ethanolamine; PA, phosphatidic acid; CHEMS, cholesteryl hemisuccinate (5-cholesten-3-ol 3-hemisuccinate); SM, sphingomyelin; EPC, egg yolk phosphatidyl choline. Data are represented as the mean ± S.D. (n=3-6).

Table S2. Primers used in the PCR to evaluate the levels of mtDNA and nuclear DNA.

PCR assays to detect the ND6 and β-actin genes were performed in order to detect mtDNA and nuclear DNA of HeLa cell lysates, respectively. ND6, mitochondrial NADH dehydrogenase 6.
