Abstract

Obesity is a state in which chronic low-grade inflammation persists in adipose tissues. Pro-inflammatory cytokines, including TNF-α, produced by adipose tissues have been implicated as active participants in the development of obesity-related diseases. Since TNF-α converting enzyme (TACE) is the major factor that induces soluble TNF-α, TACE has been noted as a pivotal regulator in this field. To reveal the role of TACE in adipose tissue inflammation, TACE-transgenic (TACE-Tg) and wild type (WT) mice were fed with high fat diet (HFD) or control diet for 16 weeks. At 13 weeks after the beginning of the diet, serum TNF-α and macrophage-related cytokine/chemokine levels were elevated in TACE-Tg mice fed with HFD (Tg-HFD mice), and the number of so-called crown-like adipocyte was significantly increased in adipose tissues of Tg-HFD mice at the end of the experiment. Although macrophage infiltration was not detected in the adipose tissues at this time, fibrosis was observed around the crown-like adipocytes. These findings suggested that TACE overexpression induced macrophage infiltration and subsequent fibrosis in adipose tissues under HFD regimen. The collective evidence suggested that TACE could be a therapeutic target of HFD-induced obesity-related adipose tissue inflammation.

Key words: adipose tissue inflammation, high fat diet, obesity, TACE, TNF-α
**Abbreviations**

ADAM: a disintegrin and metalloproteinase
CD: control diet
ELISA: enzyme-linked immunosorbent assay
HE: hematoxylin and eosin
HFD: high fat diet
MCP-1: macrophage chemotactic protein-1
PKA: protein kinase A
PMA: phorbol myristate acetate
SD: standard deviation
SDS: sodium dodecyl sulfate
TACE: TNF-α converting enzyme
TACE-Tg: TACE transgenic
Tg: transgenic
Tg-CD: TACE-Tg mice fed with CD
Tg-HFD: TACE-Tg mice fed with HFD
WT: wild type
WT-CD: WT mice fed with CD
WT-HFD: WT mice fed with HFD
Introduction

Obesity is a growing problem that threatens the health of a large population of humans in the world. The representative life-threatening disorders in obese patients are cardiovascular diseases. Pro-inflammatory cytokines, including TNF-α, produced by adipose tissues have been implicated as active participants in the development of obesity-related cardiovascular diseases (Hajer et al., 2008). Currently, obesity is regarded as a state in which chronic low-grade inflammation persists in adipose tissues (Lee et al., 2013).

TNF-α converting enzyme (TACE), also known as a disintegrin and metalloproteinase (ADAM) 17, is the major factor that induces soluble TNF-α (Gooz, 2010). TACE can cleave transmembrane proteins to release their extracellular domains from the cell surface. It is initially produced as a 120 kDa inactive protein in the cytoplasm; thereafter, the N-terminus prodomain is removed by the furin proprotein-convertase at the trans-Golgi network. Consequently, the inactive TACE is converted to a 100 kDa active form. The active form of TACE is transported to the plasma membrane and binds to its substrates on the cell surface. The effects of TACE are dependent on its diverse array of substrates, including cytokines, growth factors, and their receptors. One of the most important substrates of TACE is the membrane-bound TNF-α. TACE can convert TNF-α from the membrane-bound form to the soluble form.

In terms of the critical role of TNF-α in obesity and adipose tissue inflammation, TACE has been noted as a pivotal regulator in this field (Menghini et al., 2013). It was shown that TACE activity was significantly higher in mice fed with high fat diet (HFD) compared with chow controls (Fiorentino et al., 2010). In addition, TACE heterozygously knockout mice were protected against HFD-induced obesity (Serino et al., 2007). Furthermore, mice that lack tissue inhibitor of metalloproteinase 3,
an endogenous inhibitor of ADAM families, showed an accelerated development of complications of obesity under HFD regimen (Menghini et al., 2009; Fiorentino et al., 2010). The collective findings suggested that TACE could be a possible therapeutic target of obesity-related diseases (Menghini et al., 2013). In the present study, in order to determine how excessive expression and activation of TACE could contribute to adipose tissue inflammation, TACE-transgenic (TACE-Tg) mice and wild type (WT) mice were fed with HFD or control diet (CD).
Materials and Methods

Mice

TACE-Tg mice established in C57BL/6 line (Fukaya et al., 2013) were used. The expression of transgene, which is a heterozygously inserted mouse TACE cDNA, is driven by the β-actin promoter; therefore, the transgene-derived TACE is expressed ubiquitously. In order to distinguish from the endogenous TACE, Flag tag was connected to the 3' region of the transgene. For controls, WT C57BL/6 mice were used. Experiments using mice were permitted by the Animal Use and Care Committee (Permission No. 08-0367) and done in accordance with the Guidelines for the Care and Use of Laboratory Animals in Hokkaido University.

Diet regimen

Both TACE-Tg and WT mice (male, 12 weeks old) were fed with HFD (HFD-60, Oriental Yeast, Sapporo, Japan) or CD (AIN-93G, Oriental Yeast) for 16 weeks. The proportion of lipid-based calorie in HFD and CD was 60% and 10%, respectively. Each group, namely TACE-Tg mice fed with HFD (Tg-HFD mice), TACE-Tg mice fed with CD (Tg-CD mice), WT mice fed with HFD (WT-HFD mice), and WT mice fed with CD (WT-CD mice), included more than 10 mice.

Primary culture of hepatocytes

Hepatocytes were isolated from TACE-Tg mice and cultured as previously described (Mei et al., 2011; Tomaru et al., 2012). In order to activate TACE, 0.5 mM palmitic acid was added to the medium for 30 min at 37 °C.

Immunoblotting
Samples were homogenized in lysis buffer [0.1 % sodium dodecyl sulfate (SDS), 1 % Nonidet-P40, 0.5 % sodium deoxycholate, 100 μg/ml phenylmethylsulphonyl fluoride, 1 mM sodium orthovanadate, protease inhibitor cocktail (Complete Mini, Roche, Basel, Switzerland)]. The lysates, which were adjusted to range from 10 to 40 μg/lane, were fractionated on 7.5 % SDS polyacrylamide gel and then transferred onto PVDF membranes (GE Healthcare, Buckinghamshire, UK). After blocking by TBS-T (0.1 % Tween-20 in Tris-buffered saline) containing 2 % non-fat milk, the membranes were incubated overnight with the first antibody at 4 ºC. After 3 times wash by TBS-T, the membranes were next incubated overnight with 1:25000 dilution of peroxidase-labelled secondary antibodies (GE Healthcare) at 4 ºC. Protein bands were detected using ECL Advance Western Blotting Detection kit (GE Healthcare).

**Antibodies**

Antibodies used in this study were anti-Flag (Sigma-Aldrich, St. Louis, MO), anti-F4/80 (Abcam, Tokyo, Japan), anti-protein kinase A (PKA) (Cell Signaling Technology, Tokyo, Japan), anti-phosphorylated PKA (Cell Signaling Technology) antibodies.

**Measurement of serum TNF-α and macrophage-related cytokines/chemokines**

At 13 weeks after the beginning of the diet, peripheral blood samples were obtained from 3 mice and then the sera were mixed in each group. The serum concentration of TNF-α and macrophage-related cytokines/chemokines, including IFN-γ, IL-1β, and macrophage chemotactic protein-1 (MCP-1), was measured by enzyme-linked immunosorbent assay (ELISA) in Genetic Lab (Sapporo, Japan).
**Measurement of serum leptin and adiponectin**

At the end of the experiment, peripheral blood samples were obtained from all mice. The serum concentrations of leptin and adiponectin were determined using each corresponding ELISA kit (leptin: R&D Systems, Mineapolis, MN; adiponectin: Millipore, Billerica, MA) according to the manufacturer’s protocol.

**Statistics**

Data were presented as mean ± standard deviation (SD). Student’s *t*-test was applied for statistical analysis. The *p*-value of less than 0.05 was considered to be significant.
Results and Discussion

Activation of transgene-derived TACE by palmitic acid

Since the transgene-derived TACE was expressed as the 120 kDa inactive form, no spontaneous phenotype appeared in TACE-Tg mice (Fukaya et al., 2013). We previously demonstrated that subcutaneous injection of phorbol myristate acetate (PMA) could increase TACE activity in the skin of TACE-Tg mice compared to WT mice, which was caused by the conversion of the transgene-derived inactive TACE to the active form (Fukaya et al., 2013). Since the endogenous TACE was equally expressed in TACE-Tg and WT mice and similarly converted to the active form by PMA (Fukaya et al., 2013), the conversion of the transgene-derived TACE into the active form could be considered to reflect the higher TACE activity in the PMA-treated TACE-Tg mice than in the PMA-treated WT mice.

In this study, we first determined if the transgene-derived TACE could be activated by lipid overload using primary culture cells derived from TACE-Tg mice. Palmitic acid is a major saturated fatty acid contained in various foods. When palmitic acid was added to the medium for the primary culture of TACE-Tg hepatocytes, the 100 kDa active form of TACE was produced (Figure 1a). This finding suggested that the prodomain of transgene-derived inactive TACE could be cleaved by excessive uptake of lipids, including palmitic acid. Therefore, Tg-HFD mice could be considered as models with abundant active TACE.

High level of serum TNF-α in Tg-HFD mice

TACE-Tg and WT mice were fed with HFD or CD for 16 weeks. Serum TNF-α level was measured at 13 weeks after the beginning of the diet. It was markedly elevated in Tg-HFD mice compared with other groups, including Tg-CD mice, WT-HFD mice,
and WT-CD mice (Figure 1b). These findings confirmed that the transgene-derived TACE could be activated by HFD in TACE-Tg mice; thus, Tg-HFD mice were regarded as suitable models with abundant active TACE.

**Increased serum levels of macrophage-related cytokines/chemokines in Tg-HFD mice**

Since the feature of adipose tissue inflammation in obesity has been shown as a low-grade macrophage infiltration with circulating macrophage-related cytokines and chemokines (Surmi and Hasty, 2008), the serum concentrations of IFN-γ, IL-1β, and MCP-1 were determined. At 13 weeks after the beginning of the diet, the serum concentrations of these molecules were higher in Tg-HFD mice than those in other groups of mice (Figure 2). These findings suggested the presence of macrophage infiltration into adipose tissues in Tg-HFD mice.

**Less gain in body weight and fat weight of TACE-Tg mice given HFD**

The chronological weight gain of Tg-HFD mice was lower than that of WT-HFD mice, though it was equivalent between Tg-CD mice and WT-CD mice (Figure 3a). At the end of the experiment, the increase in body weight of TACE-Tg was significantly lower than that of WT mice (Figure 3b). Autopsy revealed lower weights especially of adipose tissues around the testis and the back of TACE-Tg mice compared with WT mice (Figure 3c).

**Histological findings of adipose tissues of Tg-HFD mice**

In order to confirm the above findings, further histological examination was conducted. Interestingly, the number of comparatively small adipocyte, so-called crown-like adipocyte which diameter is less than 10 µm, was significantly greater in the adipose tissues of Tg-HFD mice than WT-HFD mice (Figures 4a and 4b). Since the
relation of crown-like adipocytes with macrophage infiltration has been shown (Strissel et al., 2007), we conducted immunohistochemistry using the marker for macrophage, F4/80. However, macrophage infiltration was not detected in the adipose tissues of Tg-HFD mice at this time (Figure 4c). On the other hand, Masson trichrome staining demonstrated an increase in collagen fibers around the crown-like adipocytes (Figure 4d). We speculated the occurrence of macrophage infiltration into the adipose tissues in Tg-HFD mice at an earlier period in the experiment, and that fibrosis replaced the infiltration at the end of the experiment. This result is consistent with our previous report that demonstrated the accelerated fibrosis as one of the characteristics of TACE-Tg mice (Fukaya et al., 2013).

Assessments for adipocyte-related cytokines

In order to rule out the possibility that TACE-Tg mice detested taking HFD, the serum concentrations of adipocyte-related cytokines were determined. At the end of the experiment, the serum leptin levels were significantly increased while the adiponectin levels were significantly decreased by HFD in TACE-Tg mice as same as in WT mice (Figure 5). These findings suggested that TACE-Tg and WT mice were fed equivalently during the experiment.

No promotion of adipolysis in Tg-HFD mice

Next, we considered another possibility that adipolysis was promoted in Tg-HFD mice. It has been shown that adipolysis was mediated by cathecholamine-induced phosphorylation of PKA (Holm, 2003). When the phosphorylation of PKA was examined, it was rather suppressed in the adipose tissues of Tg-HFD mice compared with the other groups (Figure 6). These findings ruled out the promotion of adipolysis in Tg-HFD mice.
TACE could be a possible therapeutic target of obesity-related adipose tissue inflammation

The collective evidence suggested that TACE could be a possible therapeutic target of HFD-induced obesity-related adipose tissue inflammation. Recently, treatment with a TACE inhibitor, Marimastat, has shown to reverse steatosis in mouse models of diet-induced obesity (de Meijer et al. 2011); therefore, this is consistent with our findings. In order to prevent the development of life-threatening events in obese patients, further in vivo studies are needed to demonstrate the efficacy and safety of TACE inhibitors.

Author contributions
Y.M., A.M, T.I., and S.F. performed the experiments. U.T. and A.I. designed the research. U.T., H.M., T.A., and A.I. analyzed the data, and A.I. wrote the manuscript.
