Flora of the Island of Paramushir.

By

Yushun Kudo, Rigakushi.

Assistant Professor of Botany in the Hokkaido Imperial University.

Foreword.

In the work incidental to the preparation of this Flora of Paramushir Island, it has been my good fortune to meet with much kind assistance from all those with whom it has brought me into contact, and the publication of this article affords me a welcome opportunity for recording my appreciation of these favours. In particular I would express my sincere thanks to Professor K. Miyabe for his encouragement and advice, to Professor J. Matsumura for his courtesy in allowing me the use of the Library and Herbarium of the Botanical Institute at the Tokyo Imperial University, to Mr. F. C. Greatrex, British Vice-Consul at Hakodate, for kindly undertaking the revision of my Introduction, to Marquis Tokugawa and Mr. Yemoto for placing at my disposal their herbarium of plants collected in the Northern Kuriles in 1919, also to Professor B. Hayata, Dr. T. Nakai and Dr. H. Takeda for their valuable assistance in the work of compilation. Finally I owe a deep debt of gratitude to Mr. Fujita, Director of the Wireless Station at Otsuishi, and Mr. Hatanaka, Managing Director of the Nihon Fishery Company in the Northern Kuriles, for their collaboration in the collecting of specimens and for their never-failing kindness during my stay in Paramushir Island.

Introduction.

History of the botanical exploration of Paramushir Island.

According to Professor K. Miyabe¹⁾, the first naturalists who collected plants on the island of Paramushir were G. W. Steller and S. P.

1) Miyabe — "Fl. Kuril. p. 204."

[Jour. of the College of Agric., Hokkaido Imp. Univ., Vol. XI. Pt. 2. May, 1922.]

Krascheninnikof, who came over from Kamtschatka about 1740, and in his "Flora of the Kurile Islands" eight species¹⁾ are attributed to Paramushir on evidence supplied from the collections of Russian naturalists and naval officers by Professor Maximowicz, who has kept a record of every specimen from the Kuriles that he has seen in the herbaria of Petrograd.

So far as I am aware, the first Japanese to collect plants in this island was Churo Tarao, who visited it in 1892 as a member of the party of Baron Kataoka, Court Chamberlain, and brought back about sixty-two species. The results of the study of this collection were announced by Miyabe in Tarao's pamphlet entitled "Chishima-Tanken-Jikki"²⁾, published in 1893.

In the following year Mr. S. Yokoyama, who went to make a geological survey, collected forty-seven species of plants in various parts of Paramushir Island, and published a list of them in his geological report³⁾.

Other collections have been made at various times by travellers⁴⁾ who had occasion to visit the island, and the specimens which they obtained are preserved in the herbarium of the Agricultural College of the Hokkaido Imperial University. Mr. M. Aizawa, in particular, collected about thirty-four species⁵⁾, some of which are of considerable interest.

In 1915 Mr. Y. Kajiyama, who visited the island for the purpose of investigating its marine products, did some collecting work, and in the same year Mr. Taro Matsubara, who explored the island as a forestry expert, gathered botanical specimens in various localities.

Lastly Marquis Tokugawa and Mr. Y. Yemoto paid a visit to Paramushir in August of 1919, and made a collection of plants, most of which, through the kindness of Mr. Yemoto, I have had the opportunity of examining.

My own visit was paid in the summer of last year (1920). I first arrived at Chitose-wan by the steamer "Chifu-maru" in the evening of June 25th, spent the next day exploring that neighbourhood, and then went on to Noda-wan, where I got a motor-boat to take me to Suri-bachi on the 27th June. On the following day I walked to Okuyotsu-iwa, where I spent five days botanizing. On July 3rd a small steamer, the "Hiro-maru", took me to Murakami-wan, which is situated almost at the northern extremity of Paramushir, and has the best harbour in the whole island. Here I made a prolonged stay, my explorations taking me now through the bog-lands, now over alpine meadows, now on the rocky cliffs, now along the sandy beach. One of my excursions was to Kashiwabara-wan, a fishing cove about four miles to the south, where I obtained about fifty specimens. On another occasion a good opportunity presented itself for visiting a section of the west coast which yielded a number of interesting species, including some which I met nowhere else. On July 10th I went by motor-boat to Arakawa, a large fishing cove on the west coast, and on the following day explored in a northerly direction, round Shikata-no-ma and Nagaiwa-zaki. Then I started on a four days expedition along the west coast from Arakawa to Atenkeshi and Nishikawa,—a trip on which one passes through a wonderful variety of scenery, crossing a wide river with beautifully wooded banks, and rising from rocky or sandy beaches to lovely alpine meadows on terraces overlooking the sea. After my return to Murakami-wan on the 16th July, I had a chance of going by boat to the cape called Hirata-zaki, where I found a few interesting plants. I also took advantage of an unexpected opportunity for visiting Shirakawa on the west coast, and several valuable additions to my collection were made here. Later I made a second trip to Kashiwabara-wan, and obtained some further specimens in that neighbourhood. I finally left Murakami-wan on August 5th, proceeding by motor-boat to Ruesan, where I spent the last ten days of my stay in the island exploring forest and stream, sea-shore and cliffs.

Thus I had ample opportunities for studying the flora of Paramushir, and in the course of my explorations I procured more than one thousand specimens of 284 species of Phanerogams and Pteridophytes, all of which are now preserved in the herbarium of the College of Agriculture of the Hokkaido Imperial University. I spared no exertion in my anxiety to obtain a wide range of specimens, and I have the happiest recollections of the strenuous days I spent on Paramushir Island.

Physical Geography of Paramushir Island.

Paramushir is one of the largest islands in the Kuriles, lying about 21 miles off Cape Lobatka in the extreme south of Kamtschatka. It extends from $49^{\circ} 48'$ to $50^{\circ} 46'$ North Latitude, and from $155^{\circ} 12'$ to $156^{\circ} 10'$ Longitude East of Greenwich. It is linear-oblong in shape, about 57 miles in length by 10 miles in average width, and covers an area of some 562 square miles¹⁾. The east coast is watered by the Pacific Ocean, and the west by the Sea of Okhotsk. It is separated from Shimushu (Pervi Island) on the north-east by the Strait of Paramushir or Little Kurile, which is the narrowest channel in the archipelago, having a minimum breadth of one mile. To the south is the small island of Onnekotan, separated by the Amphitrite Strait 28 miles in width. And on the north-west is the small island of Alaid, 15 miles distant across the strait of that name. Alaid is the loftiest island of the whole Kurile Chain, its peak attaining a height of 7,460 feet, and it is also the northernmost outpost of the Japanese Empire.

Paramushir is mountainous throughout, and has many noble volcanoes, some of which are still active with steam issuing near the summit. The mountain chain, which extends roughly from north to

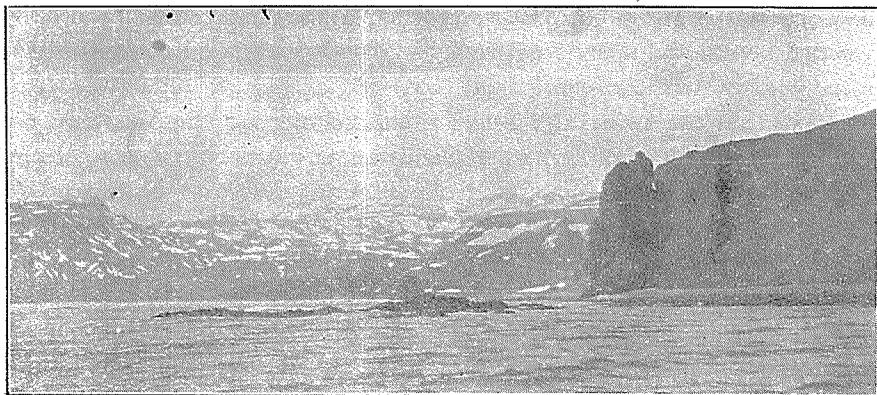

Fig. 1. A view of the northern mountain range, taken from Paramushir Strait, on July 2, 1920.

south throughout the length of the island, may be said to be divided in two by the River Todoroki. In the northern section the higher ground is towards the northern extremity, the principal peaks, reading from north to south, being Ichimonji-dake (1087.9 metres), Iwo-zan

1) Captain H. J. Snow — "Notes on the Kuril Islands" (1897), p. 76.

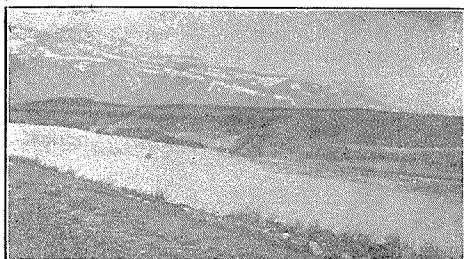

Fig. 2. A view of the southern mountain range, taken from Shiebettafu, on June 26, 1920.

tion is loftier throughout: from the cone of Chikura-dake, 1815 metres, the highest point on the island, overlooking Kujira Bay, the range runs southwards in a series of high peaks, among which the most prominent are Dai-iwo-zan (1493 m.), Neko-yama (1471 m.), Naka-dake (1227 m.), Murakami-dake (1414 m.), Kammuri-dake (1680 m.),

(1136 m.), Fujigatayama (1064 m.), Hakamagoshi-yama (1152.3 m.), Uraoka-yama (1054 m.), Byobu-dake (1161 m.), Kuroiwa-dake (1147 m.), Akaishi-dake (1106 m.), Taisho-zan (1184 m.), Yudai-zan (972 m.), Kirifuri-dake (904.5 m.), Hayanke-dake (827 m.), Takahira-dake (894.5 m.), Araki-dake (703 m.), Koma-ga-take (818.5 m.). The southern sec-

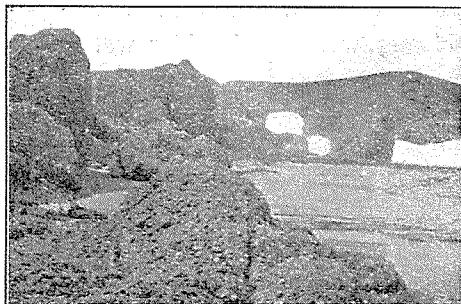

Fig. 3. A beach, near Watanabe-zaki, taken on June 28, 1920.

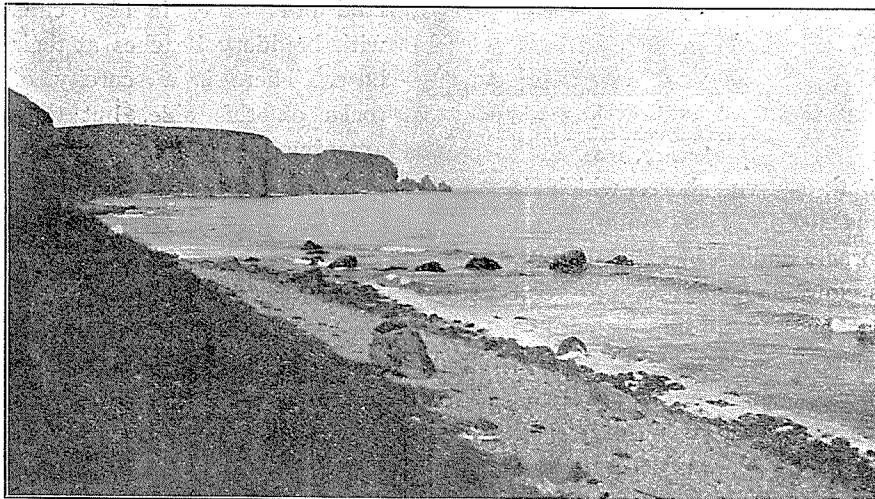

Fig. 4. A view along the sea-coast, north of Tomari-zaki, taken on Aug. 8, 1920.

Shaka-dake (1447 m.), Aka-dake (1463 m.), Yake-dake (1263 m.), Haku-en-zan (1344.6 m.), Unmu-zan (1313.5 m.), Umanose-yama (1067 m.). There is also an isolated mountain, Shiriyajiri-dake (1772 m.), which stands on the little peninsula of Shiriyajiri on the west coast of the island, a magnificent solitary cone with its graceful slopes terminating abruptly at the steep cliffs of the sea-shore.

The rivers on the western side of the island are the Ara-kawa, Kamo-gawa, Magari-gawa, Kakuma-betsu and Ni-shi-kawa; on the eastern side the Iai-gawa, Asahi-gawa, Hayanke-gawa, Masu-kawa, Kuma-gawa, Todoroki-gawa, Naka-gawa and Shiebettofu. Their gradient is mostly pronounced, and on account of

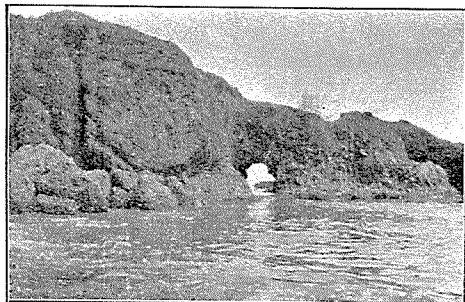

Fig. 5. Cape Watanabe-zaki, taken on June 27, 1920.

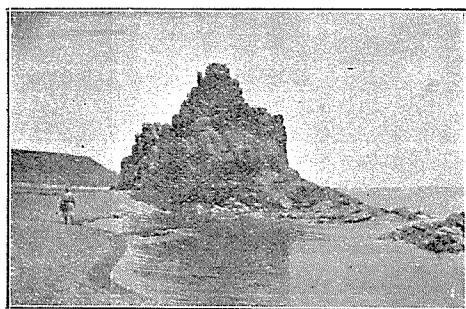

Fig. 6. A beach, in the vicinity of Kokumagawa, taken on June 27, 1920.

south-eastern shore, which is less steep. The south-eastern corner, ending in Cape Henry, is low. There are no good harbours affording complete shelter.

Scattered along the coast are numerous fishing stations operated by Japanese, few of whom remain on the island during the winter, the majority

the rapidity of the current even the narrowest streams are unfordable when in spate.

The sea-coast is boldest and steepest on the north-west or Okhotsk Sea side, where the land falls away in high cliffs with bouldery beaches at their base. There is a scarcity of rocks on this side, but they are abundant on the Pacific or

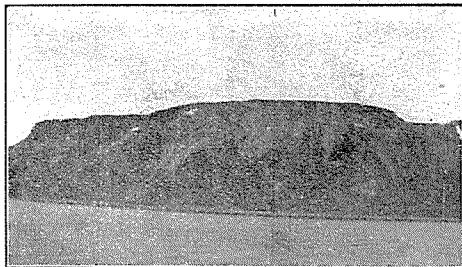

Fig. 7. A view of the sea-coast, in the vicinity of Kashiwabara-wan, taken on July 2, 1920.

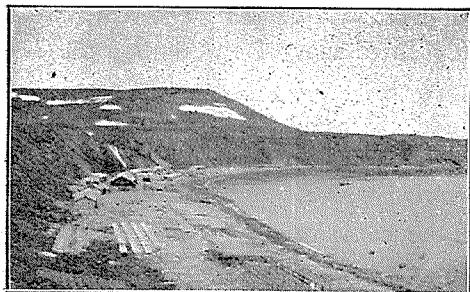

Fig. 8. A fishing station at Oku-yotsuiwa, taken on July 28, 1920.

Bears and foxes are plentiful in the island, shore birds are met with along the coast, and the streams and lagoons are frequented by water-fowl.

General climatic features of Paramushir Island.

Climate. The climate of Paramushir Island in spring, summer and autumn is, generally speaking, a moist one on account of the prevalence of fogs, though the rainfall is comparatively scanty.

From November to March the island is ice-bound, and navigation impossible.

May is cold and boisterous, with variable winds, north-westerly and north-easterly predominating, and frequent gales. During this month there is but little fog, and occasional falls of snow are recorded even during the latter half.

June has eleven to sixteen foggy days, and rain occurs during the month. Winds are very variable and light, mostly from the south-east and south-west. The temperature is 3° to $3\frac{1}{2}^{\circ}$ Centigrade in the first half of the month, rising to 7° towards the end.

July is the worst month of the year for fog, which occurs on more than twenty days. Rain is frequent, and sometimes heavy. Absolute calms or very light winds are recorded during the greater part of the month. The temperature is 7° at first, rising gradually to 10° .

August has fourteen to twenty days of fog, and some rain. Calms

coming over for the season only. Of these stations the most important are Chitose-wan, Shigivan, Noda-wan, Suribachi, Umekiya, Yotsuiwa, Ruesan, Kashiwabara-wan, Shirakawa, Dobeoi, Arakawa, Kamogawa, Atenkeshi, Nishikawa and Kujira-wan.

Roads are conspicuous by their absence in Paramushir.

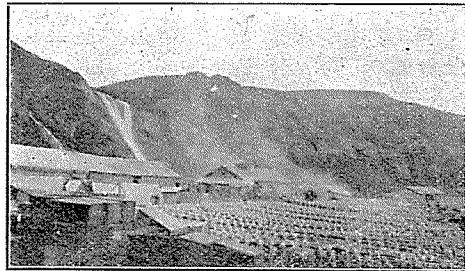

Fig. 9. A fishing station at Oku-yotsuiwa, taken on Aug. 14, 1920.

or light or north-easterly or north-westerly airs prevail. The temperature rises from 10° at the beginning to a maximum of 13° during the last ten days of the month.

In September fogs are few, and the wind blows chiefly from the north-west. Early in the month temperatures of 10° are recorded, but the weather soon becomes cold and boisterous.

Fogs. According to Snow,¹⁾ the constant fogs round Paramushir Island are caused by southerly winds passing over the warm 'Kuro-shiwo' current. These fogs are often so dense as to shut out the view completely beyond a radius of a few metres. They are usually saturated with moisture, and frequently accompanied by a cloudy sky. As a general rule they extend to a great altitude, but sometimes they occur in comparatively shallow belts above which the sun is shining from a clear sky. Their distribution varies considerably according to the direction of the wind, and the island is seldom so completely enveloped that no part of it is clear: with southerly or south-easterly breezes the north-western district is free; with a south-westerly wind the fog will lie along both sides of the island, but the extreme north-east will remain clear; with westerly, north-westerly and north-easterly breezes the fog strikes the north-west coast, and the fogless area is on the south-east side.

Currents. The Pacific coast of Paramushir is constantly washed by the strong cold current 'Oya-shiwo', which comes from the Arctic through the Behring Sea, and flows along the eastern coasts of Kamtschatka, the Kuriles and Yezo to Inuboga-saki in Honshu, where it meets the warm current 'Kuro-shiwo' coming from the opposite direction. According to Snow²⁾, coldest waters of Oya-shiwo are normally at a great depth, but are brought to the surface by the obstruction of the Kurile Islands, so that its coldest surface water in summer is met with off this archipelago.

The Okhotsk coast of Paramushir, on the other hand, is washed by the weak end of the warm current 'Tsushima-kairyu', a small branch of the Kuro-shiwo, which flows through the Strait of La Pérouse along the Okhotsk coast of Kitami Province and the Kuriles, and appears to meet a cold current coming out of the Okhotsk Sea somewhere off the east coast of Shimushu Island. It is this current (the Tsushima-kairyu)

1) Captain H. J. Snow — "Notes on the Kuril Islands" (1897), p. 47.

2) Captain H. J. Snow — "Notes on the Kuril Islands" (1897), p. 51.

that drifts to the coast of this island the large logs and timbers of Hokkaido trees, which are used on the west coast for building ships and houses and for interior woodwork.

Tides The strength of the tides is visible at all times in Paramushir Strait. On both shores of the strait the sea remains perfectly smooth, while the centre is thrown into a boiling foaming ferment of broken water, especially at the edges of the rip. The flow is to the northward and the ebb to the southward, with a speed of five to six miles per hour, causing such strong tide-races off the ends of the islands that no boat can live in them. A case is reported of a boat which was caught in the tide-rip in these straits, and capsized with the loss of all hands.

The Vegetation of Paramushir Island.

The Climax Forest. From a distance many of the hills and lower slopes of the mountains of Paramushir Island appear to be well wooded, and closer inspection reveals a most remarkable type of 'association' which, resembling the 'Krummholz' Association of Europe, must be classed as 'Forest' on account of the height of some of the woody species, which may be as much as 20 feet. The forests sometimes consist of a combination of deciduous and evergreen species, but more usually they are wholly deciduous or wholly evergreen, so that they may be divided into these two classes. The woody species forming the deciduous forest are *Alnus Maximowiczii* Call., *Sorbus sambucifolia* Roem., and *Salix paramushirensis* Kudo, while the sole constituent of the evergreen or coniferous forest is *Pinus pumila* Rgl. It is an interesting fact that in these forests we never find any representative of the genus *Sasa*, which is the commonest under-growth in the forests of the Hokkaido mainland and even the Southern Kuriles.

The Alnus Association. In the island of Paramushir the deciduous forest is represented by a single association, that of the *Alnus*, which as a general rule develops on the slopes and exposed plateaux of the mountains, on the lowlands, and along the streams. The species forming the main feature of this association is *Alnus Maximowiczii* Call., associated in some places with *Sorbus sambucifolia* Roem., occasionally with *Salix paramushirensis* Kudo, very rarely with *Pinus pumila* Rgl. In making the ascent of a hill, an unbroken expanse of this association,

with its characteristic shiny greenish tones, will often be seen stretching away into the distance as far as the eye can reach. *Alnus Maximowiczii*

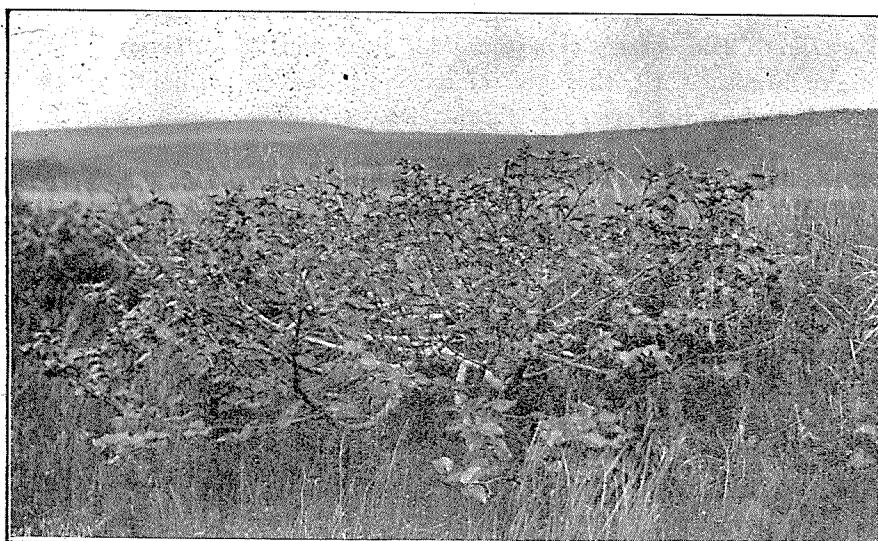

Fig. 10. *Alnus Maximowiczii* Call. in the vicinity of Murakami-wan, taken on July 7, 1920.

Call. grows mostly in the drier localities, and, though extending into more or less moist situations, is never found in boggy places. The height of the tree varies according to surroundings, and no special measurements of its stature were taken on my trip, but it may be said to range from 5 to 20 feet. The crown of this species is generally irregular in form and size, but in open situations its shape is a flattened oval. The trunk, usually 1 to 2 inches, rarely as much as 3.8 inches, in diameter, is much branched from the base, the branches and branchlets being exceedingly irregular and so intricately tangled in their growth that it is almost impossible to force a way through them. In spite of this, sufficient sunlight filters to the floor of the forest to foster the formation of an undergrowth. A list of the herbaceous vascular plants seen in the undergrowth of the *Alnus* Association is appended:—

- Dryopteris dilatata A. Gray, var. oblonga Tak.
- Dryopteris Phegopteris C. Chr.
- Athyrium Filix-femina Roth.
- Botrychium Lunaria Sw.
- Botrychium Matricariae Spr.
- Lycopodium Selago L. var. chinense Kudo.

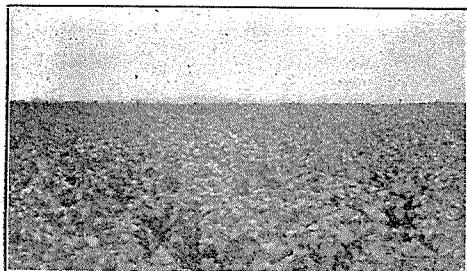

Fig. 11. An *Alnus* Association, north of Shikata-no-ma, taken on July 11, 1920.

Lycopodium annotinum L.
Lycopodium alpinum L.
Luzula plumosa E. Mey.
Majanthemum canadense Desf.
 var. *kamtschaticum* Kudo.
Streptopus amplexifolius DC.
Trillium kamtschaticum Pall.
Listera cordata A. Br.
Stellaria sachalinensis Takeda.
Corydalis ambigua Cham. et Schl.

Aruncus sylvester Kostel, var. *kamtschaticus* Maxim.
Viola Selkirkii Pursh.
Viola sylvestris Kit.
Circaeal alpina L.
Trientalis europaea L. var. *arctica* Ledeb.
Veronica Stelleri Pall.
Veronica aphylla L. var. *grandiflora* Benth.
Galium kamtschaticum Steller.
Cacalia auriculata DC. var. *kamtschatica* Matsum.

The Pumila Association. Thousands of acres are covered by this association, which is a pure impenetrable thicket of *Pinus pumila* Rgl. It differs from the *Alnus* Association in the following important respects: (1) the predominance of *Pinus pumila* Rgl. unassociated with any other woody species, and the even denser growth; (2) the total absence or poor development of undergrowth; (3) the shorter stature of the pine, and its characteristic 'pumila' form of growth. This pine creeps along the ground, and has

Fig. 12. *Pinus pumila* Rgl. at Murakami-wan, taken on July 8, 1920.

no trunk. The main branches, which may attain and even exceed a length of 10 metres, are prostrate and creeping, and emit roots; the lateral branches, ascending or ascending-spreading, commonly 3 to 5 feet high, produce a dense tangle through which it is exceedingly difficult to force a way. The impenetrableness of the thicket makes

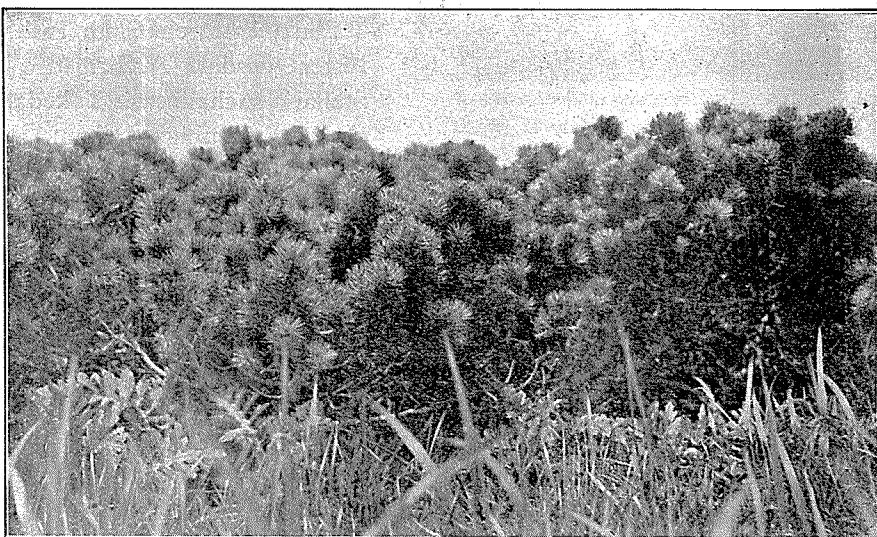

Fig. 13. *Pinus pumila* Rgl. at Murakami-wan, taken on July 8, 1920.

an accurate investigation of the manner of its growth almost impossible under natural conditions, but the charred remains on a patch of ground near Ruesan which had been burnt two or three years previously afforded excellent opportunities for studying it. These thickets form so dense a shade that only a few shade-loving plants exist under it,

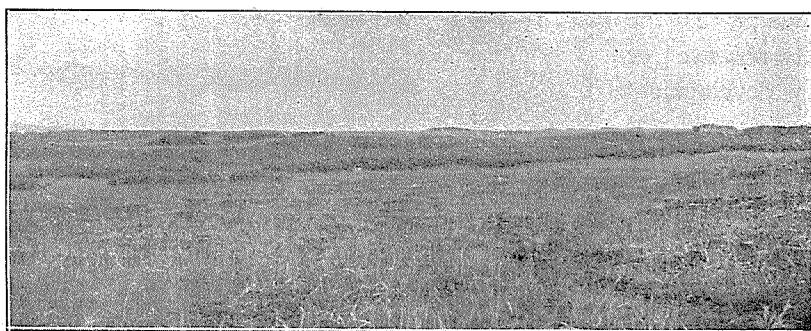

Fig. 14. A Pumila Association, in the vicinity of Murakami-wan, taken on July 3, 1920.

viz., *Circaeal alpina* L., *Linnaea borealis* L. form. *arctica* Wittrock, *Dryopteris dilatata* A. Gr. var. *oblonga* Tak., *Lycopodium alpinum* L. The Pumila Association extends all over the island, from the bay of Chitose-wan northwards to the plateaux round Murakami-wan, and it abounds on the terraces and slopes near the sea as well as on the mountains.

Factors responsible for failure in the development of trees on Paramushir Island. True alpine conditions are prevalent throughout the island, as is evidenced by the presence of an arctic-alpine flora, many species originating from arctic or sub-arctic regions being found even on the lower levels. The causes to which the presence of such an arctic-alpine flora are attributable would appear to be edaphic and climatic. The age of the formation of the island is recent. In summer the temperature is low and dense fogs prevail; during the winter the snow lies deep and the wind is strong. These alpine conditions are the factors mainly, if not wholly, responsible for the failure of trees to develop.

The Sandy-beach Association. The immediate proximity of the sea usually creates condition conducive to the maintenance of a strip of vegetation comprising a limited number of very characteristic species, and the Sandy-beach Association is a noteworthy feature along the

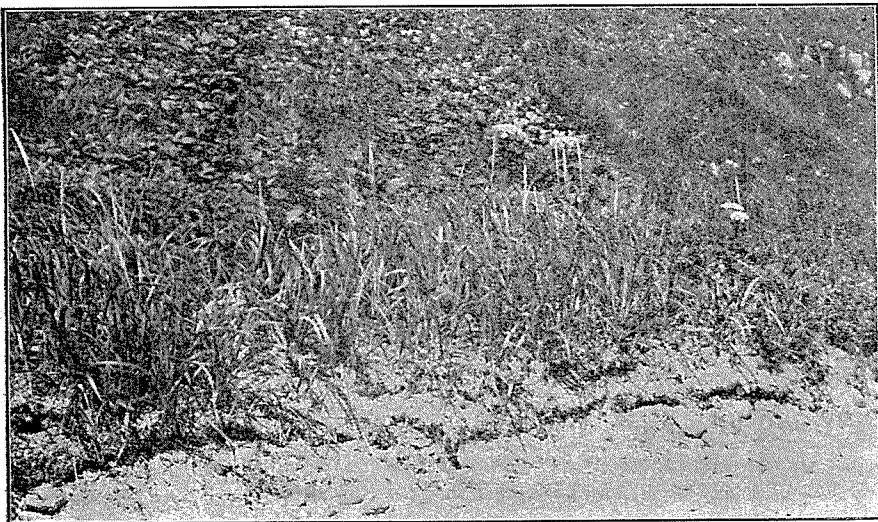

Fig. 15. *Filipendula kamtschatica* Maxim. and *Elymus mollis* Trin.
at Tomari-zaki, taken on Aug. 7, 1920.

coast of Paramushir, although sandy beaches are by no means common and few of them have reached an advanced stage of development. One of the finest displays is seen at Kashiwabara-wan on the north-east coast, and another at Magari-gawa on the west. The lower beach, near the water's edge, is usually devoid of vegetation. The middle beach is populated by a typical growth of herbaceous plants maintaining a precarious foothold on the shifting sand, and here the most important sand-loving plants to be met are :—

- Poa glumaris* Trin. var. *kurilensis* Kudo.
- Elymus mollis* Trin.
- Luzula spadicea* DC. var. *Wahlenbergii* Buch.
- Atriplex patula* L.
- Ammodenia major* Kudo.
- Lathyrus maritimus* Bigel.
- Ligusticum scoticum* L.
- Mertensia maritima* G. Don, subsp. *asiatica* Takeda.
- Senecio Pseudo-Arnica* Less.

In the next zone, or upper beach, we usually find a strip of tall herbaceous plants or occasionally shrubs forming dense thickets. Below

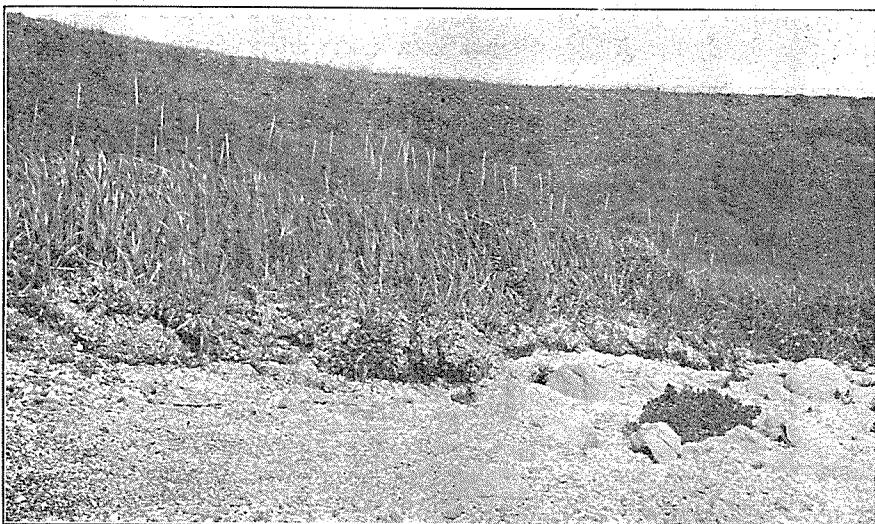

Fig. 16. *Elymus mollis* Trin. and *Ammodenia major* Kudo on the Sandy-beach Association, at Tomari-zaki, taken on Aug. 7, 1920.

is given a list of the vascular plants that occur more or less abundantly in these open tracts :—

Equisetum hyemale L.
Alopecurus alpinus Sm. var. *borealis* Ledeb.
Trisetum flavescens P. Beauv. var. *purpurascens* Arcg.
Iris setosa Pall.
Urtica platyphylla Wedd.
Aconitum kamtschaticum Willd.
Arabis japonica A. Gr.
Filipendula kamtchatica Maxim.
Rosa rugosa Thunb.
Thermopsis fabacea DC.
Geranium erianthum DC.
Empetrum nigrum L.
Epilobium angustifolium L.
Anthriscus sylvestris Hoffm.
Pedicularis Chamissonis Stev.
Anaphalis margaritacea Benth. et Hook.
Artemisia Stelleriana
 Bess.
Artemisia vulgaris L.
 var. *kamtschatica*
 Bess.
Artemisia norvegica
 Fries, f. *pedunculata*
 Kudo.
Matricaria matricarioides Porter.
 On sandy beaches developed

near river-mouths, the following interesting species are occasionally observed :—

Carex hakkodensis
 Franch.
Luzula spadicea DC.
 var. *Wahlenbergii*
 Buch.
Epilobium latifolium L.
Chrysanthemum arcticum L. var. *Gmelini*
 Kudo.

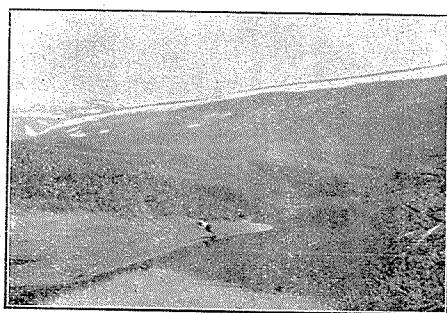

Fig. 18. A Sandy-beach Association in the vicinity of Kashiwabara-wan, taken on July 8, 1920.

The Rock Association. The first forms of life to grow on a surface of bare rock are commonly the Lichens, and other plants may be entirely absent owing to their inability to secure a foothold on the

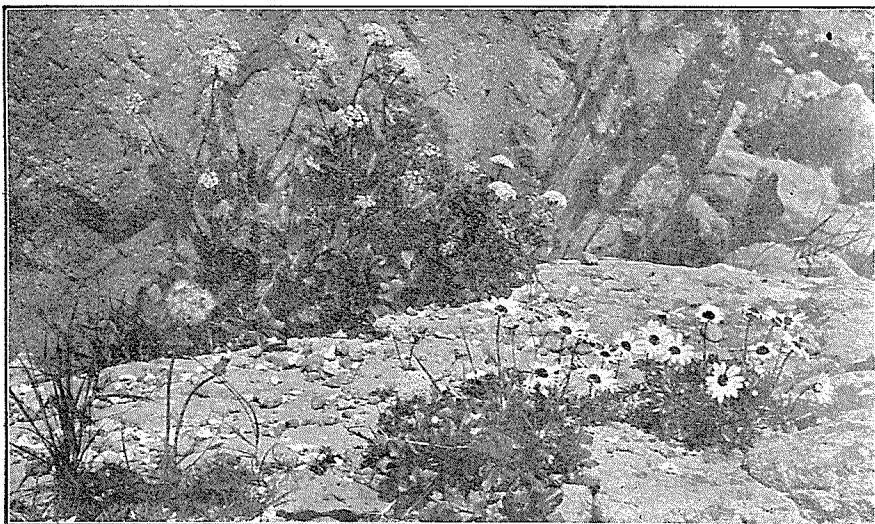

Fig. 19. A Rock Association at Tomari-zaki, showing *Chrysanthemum arcticum* L., *Ligusticum scoticum* L. and *Taraxacum ceratophorum* DC., taken on Aug. 5, 1920.

bare surface. Where, however, a certain amount of soil is present in crevices or hollows, this enables other plants to establish themselves. Of the seed-plants inhabiting such surfaces, the most important are:—

Herbaceous —

- Saxifraga bronchialis*
L. var. *cherleroides*
Engler.
- Potentilla megalantha*
Tak.
- Chrysanthemum arcticum* L.
- Stellaria ruscifolia*
Willd.
- Sedum roseum* Scop.

Cassiope lycopodioides Don;

and occasionally —

Sorbus sambucifolia Rœm.

Alnus Maximowiczii Call.

Besides the above, the following are also found :—

Calamagrostis villosa Mutel.

Elymus mollis Trin.

Juncus balticus Willd. var. *Haenkei* Buch.

Empetrum nigrum L.

Angelica refracta Fr. Schm.

Androsace Chamaejasme Host. var. *paramushirensis* Kudo.

The Dwarf-shrubby Heath Association. This is one of the most distinctive types of vegetation on the island, and is characteristically developed on exposed hill-tops and gentle slopes. In such situations the ground is sparsely covered with a matted growth of low shrubs. Among those which are peculiar to such habitats, the most conspicuous is *Empetrum nigrum* L., forming low spreading tufts, and particularly characteristic are also the four Ericaceous plants : *Loiseleuria procumbens* Desv. which straggles over the ground, *Vaccinium Vitis-idaea* L. which is intricately interwoven in the tufts, *Vaccinium uliginosum* L. occurring separately as well as among the tufts, and *Arctous alpina* Niedz. entangled in the tufts and only two or three inches high. Besides these, there is usually a sprinkling of other plants of markedly impoverished growth, such as :—

Lycopodium alpinum L.

- Trisetum spicatum* Richt.
Poa arctica R. Br.
Lloydia serotina Reich.
Majanthemum canadense Desf. var. *kamtschaticum* Kudo.
Tofieldia nutans Willd.

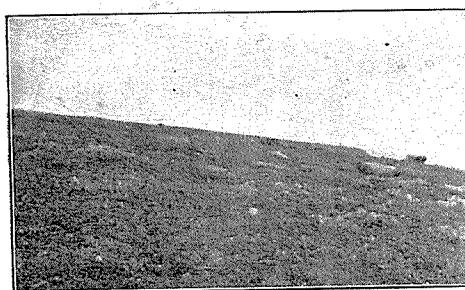

Fig. 24. A Heath Association at Nagaiwa-saki,
taken on July 11, 1920.

manent association, in other places it seems to represent a temporary stage destined to be superseded by other associations, such as the *Alnus* Association, the *Pumila* Association, the *Dwarf Rhododendron* Association, or the *Wet-bog* Association, into one or other of which it generally all but merges.

The Dwarf Rhododendron Association. This form of vegetation commonly occupies the slopes of hills. An area occupied by this association has the appearance of an irregular bushy labyrinth constructed of *Rhododendron chrysanthum* Pall. The structure of this *Rhododendron* is extremely interesting: its height is scarcely two feet, but the branches spread laterally to a radius of two to three feet or more; the leaves are thick, rugose and shiny on the upper surface; the branchlets terminate in a dense panicle of large yellow flowers. The

ground is usually covered by a luxuriant growth of undershrubs, principally Ericaceous, with which the beautiful yellow bell-shaped flowers of *Phylodoce aleutica* Makino are often intermingled. In addition to these, the plants characteristic of the Dwarf-shrubby Heath Association are well represented, but scattered and somewhat inconspicuous. The association, like the preceding one, seems to be nowhere extensively developed.

The Lowland Association. There are considerable tracts of this association, but it often passes into the Wet-bog or Dwarf-shrubby Heath associations, from both of which, however, it is easily distinguished by the taller growth of the herbaceous plants. The species of which it is made up vary greatly according to locality. The blue flowers of *Aconitum kamtschaticum* Willd., the large blue flowers of *Iris setosa* Pall., the nodding heads of *Cirsium kamtschaticum* Ledeb., the pale purple of *Geranium erianthum* DC., the orange-red of *Lilium medeoloides* A. Gray. f. *kurilense* Kudo, the rose-colour of *Rosa rugosa* Thunb.,

Fig. 25. A Lowland Association at Tomari-zaki, taken on Aug. 7, 1920.

the yellows of *Taraxacum ceratophorum* DC. and *Viola biflora* L. and the white *Trillium kamtschaticum* Pall. are all of common occurrence. Plants such as *Pleurospermum austriacum* Hoffm., *Senecio palmatus* Pall., *Angelica refracta* Fr. Schm. and *Cælopleurum Gmelini* Ledeb., which in Hokkaido attain an enormous size and grow densely, are here comparatively low in stature with a looser habit. Only one species,

namely *Filipendula kamtschatica* Maxim., attains to conspicuous size and density of growth under favourable conditions, and even in this case the same degree of development as in Hokkaido is not reached. Besides the above, the following species are found :—

- Athyrium Filix-femina* Roth.
Phleum alpinum L.
Agrostis flaccida Hack.
Agrostis perennans Tuck.
Calamagrostis urelytra Hack.
Deschampsia caespitosa P. Beauv. var. *setifolia* Ledeb.
Trisetum flavescens P. Beauv. var. *purpurascens* Arcg.
Cobresia Bellardii Degland.
Carex pyrenaica Wahlb.
Carex caryophyllea Latour.
Luzula Kjellmanniana Miyabe et Kudo.
Veratrum album L. var. *oxysepalum* Miyabe et Kudo.
Allium strictum Schrad.
Allium Victorialis L.
Lilium medeoloides A. Gray, f. *kurilense* Kudo.
Urtica platiphylla Wedd.
Thalictrum minus L. var. *nanum* Lecoy.
Barbarea orthoceras Ledeb.
Arabis lyrata L. var. *kamtschatica* Fisch.
Sanguisorba tenuifolia Fisch. var. *kurilensis* Kudo.
Aruncus sylvester Kostel, var. *kamtschaticus* Maxim.
Rubus articus L.
Anthriscus sylvestris Hoffm.
Pleurospermum austriacum Hoffm.
Cœlopleurum Gmelini Ledeb.
Heracleum lanatum Michx.
Gentiana auriculata Pall.
Swertia tetrapetala Pall.
Halenia sibirica Borkh.
Euphrasia mollis Wettst.
Pedicularis resupinata L.
Galium boreale L. var. *kamtschaticum* Maxim.
Solidago Virgaurea L.
Erigeron acre L.

- Erigeron kamtschaticum* DC. var. *hirsutum* Fr. Schm.
Achillea Ptarmica L. var. *speciosa* Herd.
Achillea sibirica Ledeb.
Artemisia vulgaris L. var. *kamtschatica* Bess.
Arnica unalaschcensis Less.
Senecio palmatus Pall.
Cirsium kamtschaticum Ledeb.
Saussurea Riederi Herd.
Picris japonica Thunb.
Taraxacum ceratophorum DC.

The Wet-bog Association. Wet bogs are quite common on the island of Paramushir. They vary in size and shape, but frequently cover an area of many acres, and are sometimes upwards of a mile in unbroken expanse. Viewed in its entirety the surface of one of these bogs may appear to be level, but viewed in detail it is seen to be more or less uneven. Various shrubby as well as herbaceous plants are scattered over these areas. Among the woody ones Ericads predominate, *viz.*, *Oxycoccus palustris* Pers. and *Andromeda polifolia* L. Three non-Ericaceous species are also usually well represented, namely two creeping willows (*Salix phlebophylla* Anders., and *Salix arctica* Pall. var.

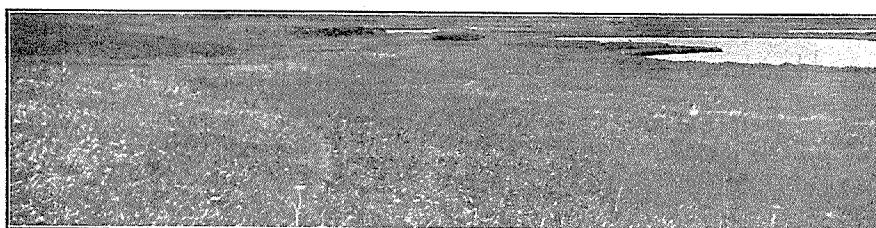

Fig. 26. A Wet-bog Association at Murakami-wan, taken on July 3, 1920.

kurilensis Kudo) and a dwarf Birch (*Betula glandulosa* Michx. var. *sibirica* C. K. Schn.). To these should be added the semi-shrubby *Geum pentapetalum* Mak. and *Empetrum nigrum* L., the latter growing abundantly in the somewhat drier parts. Two orchids are found, of which one (*Orchis Beeringiana* Kudo) is common while the other (*Platanthera tipuloides* Link.) is only occasional. *Cardamine pratensis* L. var. *kurilensis* Kudo is very conspicuous when in bloom, and other interesting species are *Drosera rotundifolia* L. and *Triglochin palustre* L., but the predominating bog herbs are those belonging to Cyperaceae and Juncaceae, *e. g.*,

- Eriophorum angustifolium* Roth.
Eriophorum angustifolium Roth, var. *majus* Schultz.
Scirpus caespitosus L.
Carex circinata C. A. Mey.
Carex hakkodensis Franch.
Carex stellulata Good.
Carex Middendorffii Fr. Schm.
Carex Lyngbyei Hornem.
Carex flaccidior Miyabe et Kudo.
Carex Buxbaumii Wahlb.
Carex rariflora Sm.
Carex Fujitae Kudo.
Carex ruesanensis Kudo.
Carex capillaris L.
Carex vesicaria L.
Carex saxatilis L.
Juncus beringensis Buch.
Juncus effusus L. var. *decipiens* Buch.
Juncus balticus Willd. var. *Haenkei* Buch.
Juncus kamschatcensis Kudo.
Juncus triglumis L.
Juncus castaneus Smith.
Juncus prominens Miyabe et Kudo.

It will be seen from the above list that nearly half the vascular herbs are Sedges and Rushes, which thus occupy a prominent position in the flora of most of the bog-lands. The following additional species may be mentioned as characteristic of wet bogs, although they also occur to some extent in other situations:—

- Equisetum arvense* L.
Equisetum palustre L.
Equisetum sylvaticum L.
Selaginella Selaginoides Link.
Iris setosa Pall.

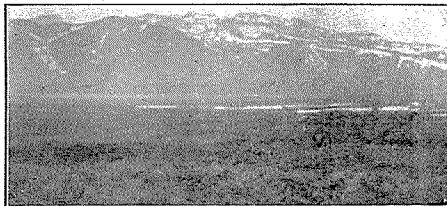

Fig. 27. A Wet-bog Association at
Shiebettofu, taken on
June 26, 1920.

- Polygonum viviparum* L.
Rumex arcticus Trautv.
Caltha palustris L. var. *parvifolia* Kudo.
Coptis trifolia Salisb.
Ranunculus reptans L.
Anemone narcissiflora L.
Thalictrum alpinum L.
Trollius patulus Salisb. var. *Riederianus* Kudo.
Parnassia palustris L.
Rubus Chamaemorus L.
Comarum palustre L.
Lathyrus palustris L.
Viola blanda Willd.
Viola palustris L.
Viola Langsdorffii Fisch.
Pyrola minor L.
Pedicularis Oederi Vahl.
Pedicularis sudetica Willd.
Saussurea Tilesii Ledeb.

In the pools and small ponds occurring here and there, the following aquatic or semi-aquatic species may be met with:—

- Potamogeton alpinus* Balb.
Eleocharis palustris R. Br.
Hippuris vulgaris L.
Menyanthes trifoliata L.
Utricularia intermedia Hayne.

Where the ground is somewhat drier, one may come across the Dwarf Pine, which seems anomalous, as this species is so essentially a denizen of the Climax Forest. A case in point is near Ruesan on the east coast.

The Brook Association. In the small ravines the banks of the streams are usually overhung with the foliage of *Alnus Maximowiczii* Call., *Pinus pumila* Rgl., *Filipendula kamtschatica* Maxim., etc., and the dense shade and still air are factors conductive to coolness and humidity. Thus the outstanding feature of such localities is the intense mesophytism, verging even on hydrophytism, of the vegetation, and the flora includes some of the most pronounced types of shade- and moisture-loving mesophytes. Among the representative species are the following:—

Equisetum arvense L.
Equisetum sylvaticum L.
Montia rivularis C. C. Gmel.
Oxyria digyna Hill.
Koenigia islandica L.
Ranunculus pygmaeus Wahlenb.
Ranunculus hyperboreus Rottb.
Cardamine umbellata Greene.
Chrysosplenium kamtschaticum Fisch.
Saxifraga punctata L.
Potentilla Anserina L.
Epilobium palustre L.
Primula eximia Greene.
Primula cuneifolia Ledeb.
Mertensia rivularis DC.
Veronica americana Schwerin.
Veronica Stelleri Pall.
Pinguicula vulgaris L. var. *macroceras* Herder.

The Wet-cliff Association. Many of the steep cliffs and outcrops of rock are kept wet by dripping water, and their vegetation consequently differs materially from that of the drier cliffs described under the Rock Association. At the same time the presence of various intermediate stages obviously prevents the drawing of a hard and fast line of demarcation, and a number of herbs of the Rock Association belong equally to the present group, while some from the Brook Association are likewise represented here. Wet cliffs are frequent on Paramushir Island, and an excellent example is to be seen at Kamogawa-zaki on the west coast, where various species of mesophytes grow on the steep face of a magnificent outcrop of rock near the sea. Some of the more or less hydrophytic types also occur there, notably mosses and liverworts, together with a few moisture-loving vascular plants.

Character of the Flora.

I. Families, genera and species of Spermatophytes and Pteridophytes.

It will be noted from the following table that the number of families of the vascular plants of the island of Paramushir is fifty-four,

the genera included in these families numbering 159, and the species totalling 284.

	Families.	Genera.	Species.
Metachlamydeæ.	16	52	78
Archichlamydeæ.	24	67	109
Dicotyledones.	40	119	187
Monocotyledones.	8	33	80
Angiospermæ.	48	152	267
Gymnospermæ.	1	1	1
Phanerogamæ.	49	153	268
Pteridophyta.	5	6	16
Total.	54	159	284

We note the entire absence of such families as Hymenophyllaceæ, Osmundaceæ, Isoëtaceæ, Taxaceæ, Typhaceæ, Sparganiaceæ, Najadaceæ, Alismataceæ, Hydrocharitaceæ, Lemnaceæ, Eriocaulaceæ, Comelinaceæ, Pontederiaceæ, Dioscoreaceæ, Saururaceæ, Chloranthaceæ, Myricaceæ, Juglandaceæ, Moraceæ, Santalaceæ, Loranthaceæ, Aristolochiaceæ, Amarantaceæ, Phytolaccaceæ, Nymphaeaceæ, Ceratophyllaceæ, Cercidiphyllaceæ, Lardizabalaceæ, Berberidaceæ, Menispermaceæ, Magnoliaceæ, Lauraceæ, Hamamelidaceæ, Oxalidaceæ, Linaceæ, Simarubaceæ, Polygalaceæ, Euphorbiaceæ, Callitrichaceæ, Buxaceæ, Coriariaceæ, Anacardiaceæ, Aquifoliaceæ, Celastraceæ, Staphylaeaceæ, Aceraceæ, Hippocastanaceæ, Balsaminaceæ, Rhamnaceæ, Vitaceæ, Tiliaceæ, Theaceæ, Stachyuraceæ, Thymelaeaceæ, Elaeagnaceæ, Lythraceæ, Alangiaceæ, Halorrhagaceæ, Araliaceæ, Clethraceæ, Myrsinaceæ, Symplocaceæ, Styracaceæ, Oleaceæ, Apocynaceæ, Asclepiadaceæ, Convolvulaceæ, Verbenaceæ, Solanaceæ, Phrymaceæ, Plantaginaceæ, Adoxaceæ, Valerianaceæ, Dipsaceæ, Cucurbitaceæ. These families are found in Yezo, where indeed most of them are common, and some are represented even in the Southern Kuriles. Among these families are included those (such as Magnoliaceæ, Lauraceæ, Anacardiaceæ, etc.) which give to the flora of Yezo that conspicuous admixture of elements from warmer regions which has been commented on by Engler¹⁾.

On the other hand, the families which we do find on Paramushir are characteristic of the cold regions, with the single exception of

1) Engler, Vers. Entwickl.-Gesch. Pfl.-welt. I. p. 18.

Rutaceæ, the occurrence of which is perhaps the most anomalous feature in the flora of the Island. This family originates in the warmer region, and is represented in Yezo by three genera, each having a single species, but in Paramushir Island it is represented only by a single genus with one species, which has berry-like fruits of a red colour. It has been discovered in only one locality, and it is very probable that the fruits of this species have been transported by birds from the Southern Kuriles.

Of the fifty-four families, the following comprise three or more genera.

Compositæ	with 16 genera.
Gramineæ }	with 11 genera.
Ericaceæ }	
Rosaceæ	with 10 genera.
Liliaceæ	with 9 genera.
Ranunculaceæ	with 8 genera.
Cruciferæ }	with 7 genera.
Umbelliferæ }	
Cyperaceæ }	with 5 genera.
Leguminosæ }	
Scrophulariaceæ }	
Caryophyllaceæ }	with 4 genera.
Gentianaceæ }	
Orchidaceæ }	with 3 genera.
Saxifragaceæ }	
Primulaceæ	

The families that are comparatively rich in species are shown in the following table, with a percentage to indicate their relative importance in the flora of Paramushir.

Cyperaceæ	with 29 species (10.21 %)
Compositæ	" 26 " (9.15 %)
Gramineæ	" 23 " (8.01 %)
Rosaceæ	" 16 " (5.63 %)
Ericaceæ	" 15 " (5.28 %)
Ranunculaceæ	" 13 " (4.58 %)
Scrophulariaceæ	" 12 " (4.23 %)
Juncaceæ	" 11 " (3.87 %)

Liliaceæ				
Cruciferæ	}			with 10 species (3.52 %)
Oenotheraceæ				
Caryophyllaceæ				
Leguminosæ	}		7	„ (2.46 %)
Umbelliferae				
Saxifragaceæ	}		6	„ (2.11 %)
Violaceæ				
Lycopodiaceæ			5	„ (1.76 %)
Polygonaceæ				
Polypodiaceæ				
Equisetaceæ				
Orchidaceæ			4	„ (1.41 %)
Salicaceæ				
Primulaceæ				
Gentianaceæ				

The genera represented by three or more species are:

- with 25 species : Carex.
- with 9 species : Epilobium.
- with 7 species : Poa, Juncus.
- with 6 species : Viola, Pedicularis.
- with 5 species : Lycopodium, Ranunculus, Artemisia.
- with 4 species : Equisetum, Luzula, Salix, Stellaria, Saxifraga, Potentilla.
- with 3 species : Dryopteris, Calamagrostis, Deschampsia, Cardamine, Geum, Vaccinium, Mertensia, Veronica, Galium, Erigeron.

There are thirty families which are each represented by a single genus, and 19 of these are represented by a single species, namely Selaginellaceæ, Pinaceæ, Potamogetonaceæ, Scheuchzeriaceæ, Iridaceæ, Urticaceæ, Portulacaceæ, Droseraceæ, Crassulaceæ, Geraniaceæ, Rutaceæ, Empetraceæ, Hippuridaceæ, Pyrolaceæ, Diapensiaceæ, Plumbaginaceæ, Polemoniaceæ, Labiatæ, Orobanchaceæ.

2. Floristic Relationship between Paramushir and neighbouring regions.

Kamtschatka. On account of the geographical position of Paramushir, a very natural conclusion would be that the flora of Paramushir

Island is most closely related to that of the southern part of Kamtschatka. This is actually the case. The number of species common to both region is 201, or 70.77 % of the whole number found in Paramushir, but it should be borne in mind that, owing to the scantiness of floristic data for Kamtschatka, this number cannot be more than an approximation, and it is very probable that the number of species common to Paramushir and Kamtschatka will be added to when the flora of Kamtschatka has been fully investigated. The following species found in Paramushir are known to occur in Kamtschatka, though not in Yezo, nor in Saghalien.

Alopecurus alpinus Sm. var. *borealis* Ledeb.

Poa arctica R. Br.

Cobresia Bellardii Degland.

Carex circinata C. A. Mey.

„ *macloviana* D'urv.

„ *lagopina* Wahlenb.

„ *ambrolepis* Trautv. et Mey.

„ *caryophyllea* Latour.

„ *saxatilis* L.

Juncus kamschatcensis Kudo.

Salix arctica Pall. (var. *kurilensis* Kudo.)

„ *anglorum* Cham.

„ *phlebophylla* Anders.

Ranunculus nivalis L.

„ *hyperboreus* Rottb.

Cardamine umbellata Greene.

„ *pratensis* L. (var. *kurilensis* Kudo.)

Saxifraga rivularis L. (var. *Laurentiana* Engl.)

Viola palustris L.

Epilobium latifolium L. (var. *arcticum* Haussk.)

„ *lactiflorum* Hausskn.

„ *Behringianum* Hausskn.

Androsace Chamæjasme Host. (var. *capitata* R. Knuth and
var. *paramushirensis* Kudo.)

Mertensia paniculata Don. (var. *pubescens* Kudo.)

Veronica aphylla L. var. *grandiflora* Benth.

Pedicularis euphrasioides Steph.

„ *sudetica* Willd.

„ *lanata* Willd.

Artemisia trifurcata Steph. var. *heterophylla* Kudo.

The closeness of the floristic relationship between Paramushir and Kamtschatka is not only to be measured by the number of common species, but the associations of vegetation of the two regions must also be taken into account. So far as is known to us, the associations of Paramushir are approximately the same as those of Southern Kamtschatka.

A study of those plants which are found in Yezo as well as in Kamtschatka and Paramushir shows conclusively that the species of northern origin are well developed in Kamtschatka and Paramushir but poorly developed in Yezo, while those of southern origin are more highly developed in Yezo than in Paramushir or Kamtschatka.

Thus we are forced to the conclusion that the flora of Paramushir bears the most striking affinity to that of Kamtschatka, not only in the number of common species but also in the plant-associations,—the comparison of which plays so important a part in the study of phytogeography.

Yezo. The species common to Paramushir and Yezo are as many as 229, or 80.63 % of the whole number of Paramushir species. They should be considered in two groups, which are quite different in the mode of their distribution. One group contains a number of southern species or plants from warmer regions, which have come from the south through Yezo and the Southern Kuriles to Paramushir, for example: *Poa acroleuca* Steud., *Carex hakkodensis* Franch., *Carex stenantha* Fr. et Sav., *Lilium medeoloides* A. Gray, *Platanthera Makinoi* Yabe, *Arabis japonica* A. Gray, *Skimmia japonica* Thunb., *Gaultheria Miquelianana* Takeda, etc. The other group contains a number of northern species, most of which are of an arctic type and are related to the Behring-Sea region as well as to arctic or sub-arctic Siberia, the Okhotsk region and Kamtschatka. Their distribution along the coast of Yezo corresponds closely with the course of the cold current Oya-shiwo, and is partly due to the favourable climatic conditions (*i. e.*, a cool and moist summer) which prevail where it flows. Thus it is interesting to note that some of these plants occur even in the southern parts of Yezo, such as Cape Erimo and Cape Yesan, where the cold current runs along the coast.

The vegetation of Yezo bears a close affinity to that of the Southern Kuriles, which will be referred to again later, and the relation between them is similar to that between Paramushir and Southern Kamtschatka. The vegetation of Yezo as well as of the Southern Kuriles is

essentially different from that of the Northern Kuriles including Paramushir; the difference becomes more obvious when we compare the plant-associations of the two regions.

The floristic relationship between the islands of Yezo and Paramushir is therefore not primary, but of a secondary nature, and would hardly seem to date back beyond comparatively recent times. The relatively large number of Yezo species which none-the-less occur on Paramushir Island may be accounted for partly by the exchange of floral elements through the agency of wind and birds, and partly by the fact that our more thorough knowledge of the flora of Yezo gives us more comparative data than have been obtained for other neighbouring regions.

Saghalien. The proportion of Saghalien species found in Paramushir is 61.27 % of the total for the latter island, and they number as many as 174. There are no species confined exclusively to Saghalien and Paramushir, but it is very interesting to note that there are some species coming down from the north which reach only as far as Paramushir and Saghalien, for instance: *Carex macrochæta* C. A. Mey (var. *paramushirensis* Kudo), *Carex rariflora* Sm., *Betula glandulosa* Michx., var. *sibirica* C. K. Schn. The remainder of the species common to Paramushir and Saghalien are distributed either in Yezo, or in Honshu, or in the Amur-Manchuria region. However, it must be borne in mind that our knowledge of the flora of Northern Saghalien is quite imperfect although that of Southern Saghalien has been exhaustively described by Miyabe and Miyake¹⁾.

As far as is known to us, the vegetation of Southern Saghalien is essentially connected, through the islands of Rebun and Rishiri, with that of the northern and north-eastern parts of Yezo, as proved by the presence of a number of conspecific plants, such as *Quercus mongolica* Fisch., *Picea Glehnii* Mast., *Abies sachalinensis* Fr. Schm., etc. Also the occurrence in the Southern Kuriles and Saghalien of *Larix dahurica* Turcz. var. *japonica* Maxim., and certain other species, is a further proof of the relationship of these islands.

The proportional data given above for plants common to Paramushir and Saghalien refer only to the flora of Southern Saghalien. And, as the vegetation of Southern Saghalien has a strong affinity to that of Yezo and the Southern Kuriles, its relation to that of Paramushir is therefore of a secondary nature, as in the case of Yezo. I cannot help

1) Miyabe, K. and Miyake, T.—*Flora of Saghalin* (1915).

thinking that the flora of Northern Saghalien would be found to bear a closer affinity to that of Paramushir than does that of Southern Saghalien, but no materials for a detailed discussion on this point are at present available.

Okhotsk-region (including Ajan). This is one of the best represented classes in the flora of Paramushir, comprising as many as 148 species or 52.11% of the whole range of Paramushir plants. The comparative strength of the floristic relationship is not to be measured by the number of common species alone, but their characters must also be taken into account. It is very interesting to find that the following species occur in both regions:— *Lycopodium alpinum* L., *Pinus pumila* Rgl., *Potamogeton alpinus* Balb., *Descampsia cæspitosa* P. Beauv., *Trisetum spicatum* Richt., *Poa cenisia* All., *Carex ambrolepis* Trautv. et Mey., *Luzula spadicea* DC. var. *Wahlenbergii* Buch., *Luzula Kjellmanniana* Miyabe et Kudo, *Juncus triglumis* L., *Tofieldia nutans* Willd., *Allium strictum* Schrad., *Salix arctica* Pall. (var. *kurilensis* Kudo), *Oxyria digyna* Hill., *Polygonum viviparum* L., *Stellaria ruscifolia* Willd., *Anemone narcissiflora* L., *Ranunculus hyperboreus* Rottb., *Thalictrum alpinum* L., *Papaver nudicaule* L. (var. *Fauriei* Kudo), *Parrya macrocarpa* R. Br., *Draba borealis* DC., *Saxifraga punctata* L., *Saxifraga bronchialis* L., *Rubus arcticus* L., *Potentilla fruticosa* L., *Geum pentapetalum* Makino, *Epilobium latifolium* L. var. *arcticum* Haussk., *Epilobium Hornemannii* Rchb., *Cnidium ajanense* Drude, *Androsace Chamaejasme* Host., *Pedicularis euphrasioides* Steph., *Pedicularis Oederi* Vahl., *Pedicularis lanata* Willd., *Pedicularis sudetica* Willd., *Linnaea borealis* L. form. *arctica* Wittrock., *Campanula dasyantha* Bieb., *Antennaria dioica* Gartn., *Chrysanthemum arcticum* L., *Artemisia glomerata* Ledeb., *Artemisia trifurcata* Steph., *Saussurea Tilesii* Ledeb., *Taraxacum ceratophorum* DC.

As far as these species are concerned, it appears that the most striking affinity of the two regions is shown by the presence of many arctic-alpine plants. The reason for this, I venture to think, is as follows: In the event of a southward migration of arctic plants in the north-eastern part of Asia, the arctic flora might be carried in two directions: (1) along the coast of Okhotsk, and (2) through the peninsula of Kamtschatka to the Northern Kuriles. On this hypothesis the presence of common species of arctic type in these regions is easily accounted for. Of course the distance between the two regions is considerable, but very little value can be attached to the distance between the

regions when considering their floral affinity. For example, it is really surprising that the mountain flora of Formosa is more closely related to that of Japan¹⁾ and of Central and Southern China²⁾ than to that of the east coast of China, from which it was not separated until the Tertiary Period. Or again, to take another instance, we know that the flora of Quelpart Island is specifically more closely related to that of Japan than to that of the Korean Peninsula³⁾.

It would be of great interest and might lead to important results if we could make a detailed comparison of the flora of the Okhotsk region and that of the Northern Kuriles, but data are lacking for a discussion on this point. However, so far as I am able to judge, an intimate floristic relation between Paramushir and the Okhotsk region is indicated by the presence of common elements of an arctic character.

Honshu. The floral elements of Honshu are well represented in the flora of Paramushir, comprising in all 175 species or 61.62 % of the whole number of Paramushir species, two in excess of the number of species shared by Saghalien and Paramushir. Most of these common species are found also in the island of Yezo. It is very interesting to notice that the alpine flora of Honshu includes a considerable number of plants that are found in Paramushir. Three species occurring in Paramushir are found on the high mountains of Honshu, although not recorded from Yezo nor even from the Southern Kuriles or Saghalien, namely, *Cobresia Bellardii* Degland, *Ranunculus pygmaeus* Wahlb. and *Thalictrum alpinum* L. *Pinguicula vulgaris* L. var. *macroceras* Herd. and *Oxytropis Pumilio* Ledeb. were formerly regarded as further examples of this peculiar distribution, but both have recently been discovered in Yezo, the former on the top of Yubari-mountain and the latter on the top of Mount Taisetsu. *Ranunculus reptans* L. has been discovered on the mountains of Honshu, Saghalien and Paramushir, but so far not in Yezo. The mysterious significance of the distribution of these species is beyond comprehension. It must however be admitted that these plants are very possibly to be found on some of the hitherto unexplored mountains of Yezo, and the presence of these arctic-alpine plants on the high mountains of Honshu is mainly of interest as affording a good example of the wide distribution of alpine species.

1) Hayata, B.—Flora Montana Formosæ, in Journ. Coll. Sc. Tokyo Imp. Univ. XXV. 19, pp. 30-33.

2) Wilson, E. H.—Phytogeogr. Sket. Formosa, in Journ. Arnold Arbor. II. pp. 39-41.

3) Takeda et Nakai, Bot. Mag. Tokyo, XXIII. pp. 46-58; Takeda, Fl. Shikotan p. 449.

Endemic species. Endemic species are comparatively few, as might be expected on an island of some 562 square miles. They are only five in number, or 1.76% of the total, and are named as follows:—*Bromus paramushirensis* Kudo, *Carex Fujiteae* Kudo, *Carex ruesanensis* Kudo, *Salix paramushirensis* Kudo, *Hypericum paramushirense* Kudo. This paucity of endemic species indicates that the flora of Paramushir is continental in origin, and also seems to denote that the formation of Paramushir Island is comparatively recent.

3. Conclusion.

In 1879 Engler¹⁾ announced his opinion that the Kuriles were an important migratory route for plants in early Tertiary times, and also in the Glacial Period from Kamtschatka to Yezo and even Honshu. In 1888, Milne²⁾ advanced the opinion, from the geological point of view, that "the Kuriles were colonized from Japan, rather than Japan colonized from the Kuriles," and that "the route by which Japan could have received its fauna is the island of Saghalin".

In 1890, Miyabe³⁾ agreed with Milne's opinion from the floristic view-point, stating that "at the time of the last great southerly migration of the rich arctic flora, Japan received her portion mostly through the island of Saghalien, and but little, if any, through the then uncompleted chain of the Kurile Islands". In 1914, as the result of a study of the flora of Shikotan — one of the Southern Kuriles — Takeda⁴⁾ arrived at the conclusion that plants which are distributed in the Southern Kuriles, Yezo and Honshu and are not found in Saghalien "must have come through the Kuriles." This is almost the same view as Engler, although he did not express it in that way. Takeda also insisted on the importance of La Pérouse Strait, which divides the islands of Saghalien and Yezo "as a primary line of demarcation". As a proof of his hypothesis, he cited a number of species which were not yet recorded from Saghalien, but were known in the Kuriles, Yezo, or Honshu. However, the subsequent study of the flora of Saghalien has revealed the existence in that island of one-third of these species. This is not

4) Takeda, Fl. Shikotan, in Journ. Linn. Soc. Bot. XLII. p. 445.

the place for a general comparative survey of the abundant data collected in Yezo and Saghalien, and more especially in their adjacent islands, but I am positive that the flora of Southern Saghalien is essentially the same as that of the northern part of Yezo. Therefore I cannot help thinking that La Pérouse Strait is not so important as Takeda considered it.

All previous authors have discussed the whole Kurile Archipelago as a single unit. To this I cannot agree. From the phytogeographical point of view, the Kuriles must be divided into at least two groups, the northern and the southern.

The southern group comprises Kunashiri, Shikotan, Etorofu and their adjacent small islands, and is generally known as the Southern Kuriles. The northern group contains the islands of Paramushir, Shimushu and Alaid, and is generally known as the Northern Kuriles. However, it is uncertain to my mind whether a number of small islands that lie between these two groups are to be considered as forming a distinct group, or whether they belong to one or other of the two before mentioned. I leave this interesting problem for future study.

The vegetation of the Southern Kuriles is composed of elements which are present also in that of the Kushiro-Nemuro district of Yezo. In the Southern Kuriles, for instance, we have such plants as the following, which are also found in the Kushiro-Nemuro district:—*Abies sachalinensis* Fr. Schm., *Picea jezoensis* Carr., *Populus Sieboldii* Miq., *Quercus mongolica* Fisch., *Quercus grosseserrata* Bl., *Ulmus japonica* Sarg., *Sorbus commixta* Hedl., *Micromeles alnifolia* Hedl., *Prunus Maximowiczii* Rupr., *Prunus serrulata* Lindl. var. *sachalinensis* Makino, *Prunus Ssiori* Fr. Schm., *Maackia amurensis* Rupr. et Maxim. var. *Buergeri* C. K. Schn., *Phellodendron amurense* Rupr. var. *sachalinense* Fr. Schm., *Acer pictum* Thunb., *Kalopanax ricinifolium* Miq., *Fraxinus longicuspis* Sieb. et Zucc., *Syringa japonica* Decne. It is a significant fact that all these species do not appear in the Northern Kuriles.

It is further to be noted that a number of species from warmer climates grow in the Southern Kuriles, such as:—*Magnolia obovata* Thunb., *Rhus orientalis* C. K. Schn., *Hydrangea petiolaris* Sieb. et Zucc., *Hydrangea paniculata* Sieb., *Ilex crenata* Thunb., *Vitis Coignetiæ Pulliat*, *Actinidia Kolomikta* Maxim., *Sambucus racemosa* L., *Viburnum Opulus* L. var. *Sargentii* Takeda.

It is true that a number of species from the cold regions, which are very common in the Northern Kuriles, are also found in the

Southern, and this may seem to indicate a close relationship between the floras of the Northern and Southern Kuriles, but the associations formed by these species in the Southern Kuriles are quite different from those of the Northern, and this peculiarity of distribution seems to be attributable to the cold and moist summer produced by the cold current Oya-shiwo.

As far as I can say with certainty from the phytogeographical point of view, the Southern Kuriles belong to Engler's Temperate-East-Asiatic Region¹⁾ and should form the northern limit of his "Provinz des mittleren und nördlichen Japans"¹⁾.

As to the flora of the Northern Kuriles, the vegetation of Paramushir Island is a good example. All the statements already made as to the vegetation of Paramushir apply equally to the flora of the other Northern Kuriles. The families appertaining to warmer regions which are distributed in the Southern Kuriles are almost disappearing in the Northern, giving place to a number of species of arctic origin which are not found in the Southern group. For instance, there are no species of the *Sasa* in the Northern Kuriles, while this genus is exceedingly common in the Southern Kuriles as well as in Yezo. These facts should suffice to illustrate my contention that the vegetation of the Northern Kuriles is essentially different from that of the Southern. Therefore, as far as the botanical evidence shows, the line which divides the Northern Kuriles from the Southern is more important than that of La Pérouse Strait or Tsugaru Strait. At the same time, it should be borne in mind that broadly speaking it is extremely difficult to draw definite dividing lines between the floral districts of these regions.

Engler sets up a province¹⁾ "Provinz des südwestlichen Kamtschatka mit Kurilen und Aleuten", and places it under the Region "Temperierte Ostasien", in which I want to understand the word "Kurilen" as the Northern Kuriles. This Province is characterised by the predominance of arctic-alpine elements, and on this account, I am strongly of opinion that it would be better to place it under Engler's "Sub-arctic Region" next to the Sub-province of "Nordostsibirien mit Kamtschatka".

*41. **Bromus paramushirensis** Kudo, sp. nov.

Rhizoma repens. Culmi basi ascendentes, erecti vel leviter curvati, striati, glaberrimi, nodis 4-5 praediti, 12-35 cm. alti. Vaginæ compressæ, teretes, glabrae vel hirsutæ, internodiis longiores præter summam illo breviorem. Liguræ hyalinæ, pallide fulvæ, apice truncatae, 1 mm. altæ, glabrae tamen apice minute ciliolatae. Laminæ linear-lanceolatae, sursum attenuatæ, tamen apice callos-o-obtusæ, basi minute auriculatae, planæ, castaneo-virides vel pallide virides, supra glabrae, subtus hirsutæ, nervis multis crassiusculis approximatis percursæ, 10-21 cm. longæ, 8-11 mm. latæ. Panicula cylindrica, erecta vel apice nutans, 8-11 cm. longa, rachi inferne et superne scabra, ramis inferioribus 2-4 nis, superioribus solitariis, omnibus filiformibus, 1.1-3 cm. longis, scabris, erectis vel erecto-patentibus, uni-spiculatis, spiculis plerumque erectis, contractis. Spiculæ linear-lanceolatae, dense 4-6-floræ, ca. 2 cm. longæ, pallide virides et violaceo-suffusæ. Glumæ steriles inæquales: I. oblongo-lanceolata apice acuminata, 3-nervata, ca. 8 mm. longa, ca. 2.2 mm. lata; II. ovato-lanceolata, apice acuta, ca. 9-10 mm. longa, ca. 3 mm. lata, 5-nervata, membranacea, utrinque glabra. Glumæ fertiles lanceolato-ellipticæ, 10-12 mm. longæ, 2.7-3 mm. latæ, 7-nervatae, dorso obtuse carinatae, apice breviter bifidæ, parum infra apicem aristam brevem exserentes, dorso longe hirsutæ, ventre et margine glabrae, arista 2.2-4 mm. longa. Palea gluma 1/2-1/3-plo brevior, ovato-oblonga, apice obtusa, valde 2-carinata, carinis ciliatis. Antheræ 2.5-3.5 mm. longæ.

HAB. In pratis siccis, prope Suribachi (Ipse! n. 4889, Julio 27, 1920).

DISTRIB. Species endemicæ!

Quod ad spicæ characterem attinet, procul dubio ad *Bromum breviaristatum* Buckl¹⁾. proxime accedere videtur. Sed planta mea differt ab illo, culmis minus elatioribus et robustioribus, foliis supra glabris, glumis sterilibus 3-nervatis, glumis fertilibus 7-nervatis.

Carex limosa L. r. *rariflora* Wahleb. in Vet. Acad. Handl. Stockholm. XXIV. p. 162.

HAB. In paludibus, prope Tomarizaki (Ipse! n. 5751, Aug. 6, 1920).—In paludibus, prope Murakamiwan (Ipse! n. 4969, Jul. 4, 1920; n. 5432, Jul. 23, 1920).

DISTRIB. Sachalin, Kuriles, Kamtschatka, terra Tschuktschorum, Europa, Alaska, ins. Sitcha, America borealis.

*65. **Carex (paniceac) Fujitae** Kudo, sp. nov.

Rhizoma stolones longos tenues emittens. Caules centrales, basi

foliati. Culmus 7-11 cm. altus, rigidulus, acutangulus, gracilis, inferne dense foliatus. Folia saepe culmo longiora, rigida, cinereo-viridia, apice longe acuminata, margine setulosa, plana, multi-striata, 2-3 mm. lata. Bractae foliaceae, inflorescentia paulo breviores, breviter vaginantes. Spiculae 3-4; terminalis ♂, linearis, 8-10 mm. longa; laterales 2-3, ♀, oblongae, sublaxiflorae, 8-11 mm. longae, breviter pedunculatae vel supraea sessilis, omnes erectae. Squamae ♀ oblongo-ellipticae, apice acutiusculae, fusco-cupreae, medio viridi-carinatae, marginibus hyalinae, 4 mm. longae, 2 mm. latae. Utriculi breviter pedicellati, trigoni, lanceo-lato-ovati, basi attenuati, apice in rostrum brevissimum ore integrum subcontracti, subcoriacei, enervosi, glauco-virides, cum pedicello 4 mm. longi, 1.6 mm. lati. Nux obovata, trigona, ca. 2.2 mm. longa, 1.5 mm. lata, viridi-castanea, laevis. Styli basis aequalis, non incrassata.

HAB. In paludibus, prope Tomarizaki (Ipse! n. 5757, Aug. 6, 1920).

DISTRIB. Species endemica!

Species *Carici trachycalamæ* Kük. Americae borealis affinis esse videtur, sed multo differt speculis ♀ non oblongo-cylindricis non densifloris, spiculis ♂ non linearis-oblongis, squamis floris ♀ non ovatis, utriculis squamas subaequantibus.

DISTRIB. var. Sachalin, Kuriles, Kamtschatka et Manchuria: sp. Sachalin, Kuriles, Hokkaido, Manchuria, Amur, Ussuri, Sibiria orientalis, Europa.

*67. **Carex (tumidae) ruesanensis** Kudo, sp. nov.

Rhizoma stolones longos subvalidos emittens. Culmus 21-35 cm. altus, tenuis, tamen strictus, striatus, laevis, basi non incrassatus. Folia culmo breviora vel aequilonga, convoluta, subfiliformia, striata, laevia, tamen margine strigulosa. Bractea inferior foliacea, evaginans, deorsum dilatata, sursum convoluta, laevis, margine strigulosa, inflorescentiam longe superans. Spiculae plerumque 2-3; terminalis ♂, elongato-linearis, breviter pedunculata, 1.5-3 cm. longa, interdum altera breviter contigua addita; laterales 1-2 ♀, apice rarius ♂, oblongae, densiflorae, 1-1.5

cm. longae, remotae, breviter pedunculatae, erectae. Squamae ♀ late orbicularis, ferrugineae, apice truncatae, acutiusculae vel obtusae, margine hyalinae, dorso trinervatae et pallidae, ca. 3 mm. longae, ca. 2.5 mm. latae. Utriculi squamis minores, paulo breviores, orbiculari-ovati, turgido-trigoni, 2.3 mm. longi, 2 mm. lati, fusco-olivacei, glabri, apice dense brunneo-punctati, nervis 2 lateralibus prominentibus percursi, ceterum obsolete nervosi, apice in rostrum breve, ore emarginato-bidentulum abrupte abeuntes. Nux oblonga, parva, laxe inclusa. Styli basis aequalis. Stigmata 3, mediocria.

HAB. In paludibus, prope Ruesan (Ipse! n. 5839, Aug. 11, 1920).

DISTRIB. Species endemica!

Species distinctissima, soli *Carici olivaceae* Boott Asiae orientalis et australis proxime affinis, (quarum specimina authentica non vidi, vero comparavi specimina japonica) quae tamen culmis validioribus elatioribus 60-90 cm. altis, basi incrassatis, foliis 6-16 mm. latis, bracteis evaginatis, spiculis 5-8 in numero, crassioribus, squamis oblongo-lanceolatis abunde differt. Statura vero, modus crescendi, magnitudo fere dissimilis.

DISTRIB. Kuriles, Kamtschatka, ins. Behringii, America arctica.
 Hæc species ad floram japonicam nova est!

*101. *Salix* (vinales) *paramushirensis* Kudo, sp. nov.

Frutex 0.6-1.5 m. altus, valde ramosus; ramuli crassi, castanei vel fusco-castanei. Folia breviter petiolata, oblanceolato-oblonga, oblongo-elliptica, apice acuminata vel acuta, basi cuneato-attenuata, supra viridia, nitida, subrugosa, subtus pallidiora, glauciuscula, utrinque glabrata, margine subcrenulata, revoluta, 5-7.5 cm. longa, 1.0-2.2 cm. lata, petiolis 3 mm. longis; costa nervisque prominulis, tenuiter subreticulata, nervis sub 40°-50° a costa divergentibus; petioli basi subdilatati, superne laxe pilosi, 2-6 mm. longi. Amenta coætanea, brevissime pedunculata; pedunculis foliatis, foliis ovato-oblongis, oblongo-ellipticis, minoribus, 8-12 mm. longis, 3-5 mm. latis, margine longe albo-ciliatis, utrinque subglabris vel minute puberulentibus. Amenta mascula cylindrica, 1.5-2 cm. longa, ca. 1.1 cm. lata, rhaci sericeo-villosa; bractæ elliptico-oblanceolatae, apice obtusa, deorsum oblongæ, margine longe albo-ciliatae, ca. 2 mm. longæ, 0.9 mm. latæ; glandula una, ventralis, linearis, 0.9 mm. longa, apice capitato-truncata; stamina 2, filamentis liberis, ca. 5-6 mm. longis, glabris; antheris oblongo-orbicularibus, 0.5 mm. longis. Amenta fœmina cylindrica, 1.5-2 cm. longa, 0.9-1.0 cm. lata; rhaci sericeo-villosa; bractæ oblongæ, apice rotundatae, longe albo-ciliatae, ca. 2.3 mm. longæ, 0.6-0.7 mm. latæ; glandula una, ventralis, ovato-linearis, apice truncata, ca. 1 mm. longa. Ovarium pedicellatum, oblongo-ovovatum, dense sericeo-villosum, ca. 2.1 mm. longum, ca. 1.2 mm. latum, pedicellis sericeis, 7-8 mm. longis, stylis strictis, ca. 8 mm. longis, stigmatibus profunde bi-divisis.

HAB. In pratis, ad rivulos, prope Nodawan (Ipse! n. 4865, Jun. 26, 1920).—In pratis siccis, prope Murakamiwan (Ipse! n. 5005, Jul. 6, 1920).—In pratis siccis, inter Nish kawa et Atenkeshi (Ipse! n. 5210, Jul. 13, 1920).—Ichaniumbets (S. Yokoyama! Sept. 8, 1893).

DISTRIB. Species endemica!

Species hæc proximæ affinis est *Salici opacæ* Anders., sed ea facile dignoscitur, truncis valde ramosis, foliis oblanceolato-oblongis vel oblongo-ellipticis, prominente nervosis, amentis brevioribus, stigmatibus 2-divisis.

Guttiferæ.

*179. *Hypericum kamtschaticum* Ledeb. in Denkschr. Bot. Ges. Regensb. III. p. 131 et Fl. Ross. I. p. 447; Maxim. Mél. Biol. XI. p. 170; Yabe et Yendo, Bot. Mag. Tokyo, XVIII. p. (188); Matsum. Ind. Pl. Jap. II. 2. p. 366.

HAB. In pratis siccis, prope Tomarizaki (Ipse! n. 5709b, Aug. 7, 1920).—In pratis siccis, prope Nagaiwasaki (Ipse! n. 5129, Jul. 11, 1920).

DISTRIB. Kuriles, Hokkaido et Kamtschatka.

Planta nostra ob folia parce nigro-punctata, amplexicaulia, late ovata vel ovato-rotundata, apice rotundato-emarginata, cymas foliatas paucifloras, pedicellos folio florali breviores, anthers glandula nigra innatas, spectare mihi videtur ad *Hypericum kamtschaticum* Ledeb., cuius tamen specimina authentica conferre mihi non licuit. Variat etiam stylis 3-4 in numero.

*180. *Hypericum paramushirensis* Kudo, sp. nov.

Caulis tenuis, ascendens, teres, simplex vel apicē leviter ramosus, glaber, 15-22 cm. altus. Folia sessilia, ovato-rotundata, ovato-elliptica, elliptica, basi rotundata, obtusa vel subcordata, apice emarginata, obtusa, rotundata vel rarius truncata, 1.4-2.7 cm. longa, 1-1.7 cm. lata, papyracea, supra viridia, subtus pallidiora, margine obsolete undulata, utrinque glabra, dense pellucido-punctata, prope marginem paucē nigro-punctata, nervis teneris. Cyma terminalis, pauci-flora. Calycis laciniae 5, foliaceæ, valde inæquales; majores oblongo-ellipticæ, purpureo-marginalitæ, et nigro-punctatae, 7 mm. longæ, 3.5 mm. latae; minores oblongo-lineares, 5-6 mm. longæ, margine nigro-punctatae. Petala 4, obovata, sursum cuneata, apice truncato-obtusa, basi cuneata, ca. 1.2 cm. longa, 6 mm. lata. Stamina triadelpha, filamentis stylis paulo longioribus, antheris subglobosis nigro-maculatis. Styli 3-4, ovario paulo longiores, leviter curvati. Ovarium late ovatum, bruneo-striatum. Capsula mihi ignota. Semina mihi ignota.

HAB. In pratis siccis, prope Ruesan (Ipse! n. 5668, Aug. 5, 1920).—In pratis siccis, prope Tomarizaki (Ipse! n. 5909, Aug. 7, 1920).—In pratis siccis, prope Shirakawa (Ipse! n. 5595, Jul. 30, 1920).

DISTRIB. Planta endemica!

Species haec procul dubio ad *Hypericum kamtschaticum* Ledeb. prope accedit, differt tamen foliis distincte pellucido-punctatis, floribus leviter minoribus. Specimina nostra optime congruunt cum descriptione *Hyperici paradoxi*, sed floribus non tetrameris facile dignoscitur.
