## Introduction

As already reported, ${ }^{(48)}$ many theories and equations have been proposed in the kinetics of enzymes. The author has made it certain that no one of the equations can be applied generally even for one kind of enzyme but each of them can be accepted as apparently applicable to the data of special cases. In the investigation of soy bean protein the author decomposed it with pepsin, pancreatin and papain, taking the length of time, the relative quantity of enzyme or the quantity of substrate as a variable. He endeavoured to find some equation applicable well with no exception at least to his data. He could find some equations applicable well with no exception at least to his data. He tried to apply the equations to many published data. The results were satisfactory for many enzymes. One of the equations was always better applicable than any one ever before proposed according to the kind of enzyme or to the kinds of enzyme and substrate. He tried to examine the principal theories or equations in the kinetics of enzymes proposed by preceding investigators. He can point out some defects or mistakes in them. The author wonders by what examination they determined the applicability of their equations. He proposes several items for examining the applicability of equations most of which have not been taught in enzyme chemistry or perhaps in the kinetics of general chemistry for these several decades. Furthermore he is going to propose some new equations which will have wide application. Not only to data obtained in experiment with time but also to data with the relative quantity of enzyme or the quantity of substrate as a variable, do the equations seem to be satisfactorily applicable.

## Decomposition taking time as a variable

## 1. Nomenclature of equations to be proposed

Nakamura's equation, $\frac{1}{t^{b^{\prime}}} \frac{x}{a(a-x)}=K$ and the equation, $\frac{1}{t^{k^{\prime}}}$ $\log \frac{a}{a-x}=K$ which was formulated by the present author were

[^1]applied to the data obtained by the latter in the decomposition of protein and oil with various enzymes. The modified forms of these equations were also applied to the data obtained in the decomposition taking the relative quantity of enzyme or the quantity of substrate as a variable. The author considersed that Nakamura's equation was the general form of the bimolecular equation and that his own equation was the general form of the monomolecular equation. In the same manner, the general form of higher orders,
$$
\frac{1}{t^{c^{\prime}}} \frac{1}{n-1}\left\{\frac{1}{(a-x)^{n-1}}-\frac{1}{a^{n-1}}\right\}=K
$$
is considered. These general forms are here, for the sake of convenience, named as follows:
\[

$$
\begin{aligned}
& \frac{1}{t^{k^{\prime}}} \frac{x}{a(a-x)}=K \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots . . \text { T.N.N..................... } \\
& \frac{1}{t^{t^{t^{c}}}} \frac{1}{2} \frac{2 a x-x^{2}}{a^{2}(a-x)^{2}}=K \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots . . \text { T.N.N.................. } \\
& \frac{1}{t^{t^{2}}} \frac{1}{n-1}\left\{\frac{1}{(a-x)^{n-1}}-\frac{1}{a^{n-1}}\right\}=K \ldots \ldots \ldots . . \text { T.N.N.N, }
\end{aligned}
$$
\]

where T is the capital letter of Tadokoro, under whose leading the author proceeded with the study, the second N that of Nakamura who is the finder of the equation of T.N.N. II itself and the third N denotes Nakajima, the finder of T.N.N.I and the proposer of T.N.N. equations as generally applicable equations. Each, I, II etc., shows the order of the equation when each $k^{\prime}=1$. The author is going to propose these T.N.N. equations as general equations in the kinetics of enzymes.

## 2. Meaning of the application of the kinctic equation and examples showing the imperfection or mistakes of some kinetic theories

If we strictly examine the applicability of equations each of which has been proposed to be well applicable to some data, we can recognize that some of them are of true application while the others are only of apparent application. According to the writer's examination and opinion most of the equations which have been proposed in enzyme kinetics are of the latter kind. If the application of an equation is only
apparent, it has no direct relation with the chemism or chemical nature of each component though the applicability may be very high. But the equation of true application is considered to give suggestions regarding the chemism. In the chemical change between two components whose chemical structures relating to the change are known, we can understand that the true-application kind of equation has a close relation to the structure of both components or to the chemism between them. And on the other hand we can also suggest the structure of the chmicals by the true-application kind of equation. For instance we can suggest the chemism between two components by the true application of the monomolecular or the bimolecular equation. Therefore a truly applicable equation is a key to open the unknown chemical nature of components or the chemism between two components. Because of this important significance of the application of equations, many investigators have endeavoured to find such equations, and notwithstanding their endeavour the apparently applicable equations have little value, while on the contrary, as the equation of true application has such an important meaning, the apparently applicable equation which was considered mistakenly to be truly applicable by each author made him often reach a mistaken theory. Northrop's theory which was introduced by the mistaken acknowledgement of the Schütz law is such an example. ${ }^{(48)}$ The present author has examined many theories and equations in enzyme chemistry proposed by preceding investigators to try to find some truly applicable equations among them, but the endeavour was not requited with success. He was able unexpectedly to point out defects in many theories or the mistaken application of equations. Some of them are shown below.

## 1) Arginase

Gross ${ }^{(29)}$ decomposed arginine with arginase, to the data of which he applied the monomolecular equation and obtained the result given in Table I. Gross attended to two facts. (i) As shown in the table the value of $K$ decreases with the increase of decomposition-time. (2) After 24 hours of decomposition he added 5 cc . of enzyme solution. Two hours after the addition, the decomposition proceeded to $75 \%$ with an increase of only $3 \%$. From these two facts the author considered that the decomposition velocity decreased markedly and attributed it to the injurious effect of the decomposition product-ornithine. The present author applied T. N. N. II to his data with the result given in Table II. The equation is surely well applicable. Gross suggested the velocity
of decomposition by arginase from the premise that the decomposition followed the monomolecular equation, which premise made him reach his conclusion. But although the value obtained in the decomposition by the further addition of a comparatively large amount of enzyme was so little as $3 \%$, it cannot induce his conclusion. In this case the quantity of substrate was little and the decomposition must have followed also T. N. N. II with the values of $K$ and $k^{\prime}$, which are quite different from those in the first step of decomposition. The writer thinks that the decomposition velocity has no relation to the monomolecular equation. Therefore the two facts pointed out by Gross give no reason to accept the theory of the injurious effect of ornithine.

## 2) Invertase

In the kinetics of invertase many theories and equations have been proposed. Michaelis and Menten ${ }^{(41)}$ deduced an equation from theoretical examination. Their equation coincides with Henri's equation formulated independently. The two equations are given below.

$$
\begin{aligned}
& \frac{1}{t}\left(\frac{1}{a}+\frac{1}{k_{1}}+\frac{1}{k_{2}}\right) a \cdot \ln \frac{a}{a-x}+\frac{1}{t}\left(\frac{1}{k}-\frac{1}{k_{1}}-\frac{1}{k_{2}}\right) x=\text { const. } \\
& m \cdot \ln \frac{a}{a-x}+n \cdot x=t \cdot \text { const. }
\end{aligned}
$$

Although Michaelis and Menten deduced their equation from careful examination it does not always agree with experimental results. After examining the examples which were shown by the authors to prove their theory and equation to be true, the present author cannot accept their proof. One of the examples is given in Table III. The values of $K$ are apparently uniform. But the two extremes are 0.0407 and 0.0496, the ratio of which is not so small, as it is 100:121.9. Moreover the range of decomposition is so very narrow as to be under $20 \%$. Within such a narrow range one must be careful especially as to the uniformity of the values of $K$ and the increasing or decreasing tendency of the value of $K$. Their experimental results cannot satisfy these important examinations. Michaelis and Menten's theory was studied by many investigators and was said to have many defects both in the theoretical and experimental researches. ${ }^{(64)}$ It seems that the deeper the theoretical research the more difficult it is to find a satisfactory equation. The present author is going to apply T.N.N. equations to Michaelis's data and examine the applicability of them. The data
of the widest range of decomposition among the original examples shown in Table IV are taken. The applied result of T. N. N. I to the data is given in Table V. As shown in this table, each difference between experimental and calculated values is large and the equation cannot be said to be well applicable. But in the application of equation one or two special data in an experimental result occasionally give to the whole calculated result such a deviation as makes one misjudge the applicability of the equation and suppose it is not true. For trial the writer applied again the equation to the above data omitting the last term as Michaelis did for this result in the original paper. The calculated result is given in Table VI, where the applicability is accepted to be satisfactory. For the data here taken, the values of $K$ of Michaelis's equation are not uniform, as their two extremes are 0.0405 and 0.0489 and their ratio is $100: 120.7$.

The author has examined Michaelis and Menten's equation using their own experimental results and shown the defect of it. The applicability of his equation, T.N.N.I, to the same data is proven above. Therefore their theory is considered also imperfect. The premise of the impossibility of finding a satisfactory equation in the kinetics of invertase seems to disappear.

## 3) Catalase

Issajew ${ }^{(37)}$ obtained catalase solution from yeast, and applied the monomolecular equation to his data. The data was considered by him to follow the equation. Eulek ${ }^{(21)}$ considered in the same manner his data obtained with fungus extract. Faitelowirz ${ }^{(88)}$ obtained data with milk catalase to find some applicable equation. In the decomposition at $25^{\circ} \mathrm{C}$ with a large quantity of catalase for dilute substrate, it followed the monomolecular equation but the decomposition velocity for the substrate was thought to decrease with the progress of the decomposition of the catalase itself. The decomposition of catalase was thought to be weaker for high concentration than for low concentration of $\mathrm{H}_{2} \mathrm{O}_{2}$. For a definite concentration of $\mathrm{H}_{2} \mathrm{O}_{2}$ the increase of decomposition velocity was comparatively little and was not proportional to the increase of catalase. $\mathrm{BACH}^{(7)}$ studied the catalase of sebaceous tissue. In the decomposition of much $\mathrm{H}_{2} \mathrm{O}_{2}$ with much catalase he thought that the decomposition took place proportionally to the quantity of substrate or enzyme. SENTER ${ }^{(69)}$ thought that his data obtained with blood catalase followed the monomolecular equation. Morgulis ${ }^{(47)}$ recognized that the
decomposition by catalase took place proportionally to the quantity of enzyme or substrate. When much quantity of the enzyme was taken, the monomolecular eqnation was well applied, while in the decomposition of under $2 / 3-4 / 5$ part of the substrate the bimolecular equation and, in the decomposition of medium degree, the $1 \frac{1}{2}$ molecular equation was applied well to the data. Rona and Damboviceanu accepted Morgulis's conclusion. They applied equations to their data as given in Table VII.

In the decomposition of $\mathrm{H}_{2} \mathrm{O}_{2}$ by catalase, Yamazaki ${ }^{(85)}$ supposed two independent processes the velocity of each of which was considered to be constant through the entire decomposition. Each velocity was given as follows:

$$
\begin{aligned}
& -\frac{d \mathrm{E}}{d t}=K \\
& -\frac{d c}{d t}=k \mathrm{E} c
\end{aligned}
$$

where $E$ denotes the concentration of enzyme, $c$ the concentration of $\mathrm{H}_{2} \mathrm{O}_{2}, K$ and $k$ are constants. By integration,

$$
\log \frac{\mathrm{C}_{o}}{c}=\log \frac{\mathrm{C}_{o}+a}{c+a}=k^{\prime} a t
$$

was obtained where $\mathrm{C}_{o}$ denoted the concentration of $\mathrm{H}_{2} \mathrm{O}_{2}$ at the beginning of decomposition, $c$ the concentration after $t$ hours, $k^{\prime}$ equals $k K$, and a the integration constant. He made many elaborate experiments. Maximowitsch and Awronomova ${ }^{(44)}$ also supposed two processes in the decomposition by catalase such as,

1. Decomposition of $\mathrm{H}_{2} \mathrm{O}_{2}$ by catalase,
2. Breaking of catalase by $\mathrm{H}_{2} \mathrm{O}_{2}$
which were denoted as given in the following equations

$$
\begin{align*}
& \frac{d x}{d t}=C(A-x)(B-y)  \tag{I}\\
& \frac{d y}{d t}=C_{1}(A-x)(B-y) \tag{2}
\end{align*}
$$

where $A$ and $B$ mean the concentration of $\mathrm{H}_{2} \mathrm{O}_{2}$ and the concentration of catalase both at the beginning of decomposition respectively, $x$ the quantity of $\mathrm{H}_{2} \mathrm{O}_{2}$ decomposed in $t$ hours, $y$ the quantity of enzyme decomposed in $t$. As $C \neq C_{1}$, deviding (2) by (I) $\frac{d y}{d x}=\frac{C_{1}}{C}$ results,
which will be represented by $E$, and $\frac{B}{E}$ will be denoted by $D$. The authors obtained finally the equation,

$$
C_{A H}=\frac{1}{t} \frac{1}{A-D} \log \frac{D(A-x)}{A(D-x)} .
$$

From the data of their experiment they calculated the values of the constant of their equation, and they thought that their equation was perfectly applicable. As they said, although the equations of Maximowitsch and Yamazaki are different from each other in form, they each deduced independently their respective equation from the same point of view. Therefore the meaninings or the values of applicability of their two equations are quite the same.

The principal kinetic theories of catalase are given above. The author will show hereafter the incompleteness or defect of some equations. The incompleteness or defect of these theories from which the equations were deduced will be accordingly understood. The applied results of T. N. N. equations will be given at the same time to show the good application of them. The result obtained by Issajew in the application of the monomolecular equation is given in Table VIII. As seen in this table, the uniformity of the values of $K$ is constant. The writer applied T. N. N. I and II equations to the same data as given in Table IX. As the probable error for equation $I$ is very near to I , the monomolecular equation can be said to be satisfactory. The same conclusion can be deduced from the result when applied to another example as shown in Table X.

EULER recognized the good application of the monomolecular equation to his data obtained by catalase of shaggy boletus which are given in Table XI. The present author applied T. N. N. equations to Euler's data, from which T. N. N. II is clearly accepted to be satisfactory as shown in Table XII. From the results of the application in this table it seems that the applicability is high in the order of T.N.N. II, T. N. N. I and the monomolecular equation.

Senter recognized the satisfactory application of the monomolecular equation to his data, obtained by blood catalase as given in Table XIII. To the same data the present author applied T. N. N. equations. T. N. N. I is distinctly better applicable than II and the value of $k^{\prime}$ of T. N. N. I is almost equal to 1 as shown in Table XIV. Therefore
no perceptible difference of applicability can be seen between the monomolecular equation and T. N. N. I.

Next T. N. N. equations will be compared with Yamazari's equation for his same data. From many results of Yamazaki some of them were taken at random to which T.N.N. equations were applied as given in Table XV where T. N. N. I is distinctly better applicable than II or Yamazaki's equation. The value of $k^{\prime}$ of the last equation is first large and becomes little and so the equation is not adequate to maintain his theory. Yamazaki himself pointed out the defect of his equation in this fact. To his data, T. N. N. I was always best applicable, examples of which are shown in Tables XVI-XIX.

The applicability of Maximowitsch and Awtonomova's equation will be next examined. The proof of the equation by the authors is to be regretted in soma points. First, although they gave many experimental results these are not adequate to examine the applicability of an equation because the range of decomposition is not wide. The present author calculated the range by the formula $\left(x_{e}-x_{f}\right) / a \times 100$ where $x_{e}$ is the quantity of substrate decomposed for the longest time, $x_{f}$ that for the shortest time and $a$ is the quantity of substrate taken. From the data of Maximowitsch, the present author calculated the ranges for all results, some of which is as little as only about 2 to $7 \%$ and even the widest range is about $35 \%$. Secondly, to calculate each value of the constant of their equation, he took the mean value of $D$ of his equation by averaging the calculated results of a very indefinite number, for instance, they took the mean value of $D$ from 10 calculated results for 6 experimental data of one group, while in some other case they took the value averaging only 3 or 4 calculated results for 6 data of another group. At any rate the present author applied T. N. N. equations to their data. T. N. N. I was always better applicable than II. Some examples are shown in Tables XX-XXVII. As seen in these tables the values of $D$ are not quite uniform. When the values of $K$ of the monomolecular equation are comparatively given, the values of $C_{B}$ seems very uniform, but the two extremes are 32 and 29 which are $10 \%$ different from each other. On the other hand, T. N. N.I is satisfactory. In other examples the same defects of Maximowitsch's equation as explained in the previous example can be pointed out while T. N. N. I shows always good application.

Some of the data of Rona and Damboviceanu, which were shown by them to follow $1 \frac{1}{2}$ molecular equation as Morgulis's theory will be
given. To these data T. N. N. II shows its perfect applicability as shown in Table XXVIII and XXIX.

## 3. Necessary items for examining the applicability of equations

In the examination for applicability of an equation several items must be mentioned. If one or two of them are overlooked it is usual to overestimate the applicability of the equation. However, such important items have never been taught in enzyme chemistry although one or two of them were usually attened to in each of the preceding studies on kinetics. The author considers that at least all the following several items are to be attended to in examining the applicability of equations.
(A) For the experimental data in regard to which the applicability is to be examined, it is necessary to attend to the following:
(i) Range of decomposition

If a certain equation is applied to data with the range of decomposition ( $x_{1}-x_{2}$ ) \%, the applicability is to be discussed only within that range of decomposition. Even if it is proved to apply well for that range, the applicability to the data beyond that range is quite uncertain. If the application is proved to be true for a wide range of decomposition, it holds true for a narrower range. Therefore, one must attend to the applicability of the equation as well as to the range of decomposition for the applied data. To make clear such an explanation, consider an experimental result with its plotted curve on coordinates. If a short part of the curve be taken, it can be treated as a straight line or as the curve of some other kind without much impropriety. If a long part of the curve be taken, the impropriety caused by such treatment cannot be negligible. There have been many studies which treated the data within only several $\%$ of decomposition to examine the applicability of equations, but such an examination, or the equation whose applicability was proved with data of such a narrow range of decomposition, has almost no meaning or value.
(ii) The number of experimental terms should not be feru

If an equation is applied to data of few terms the applicability is often mistakenly estimated. Consider that many points for experimental data are arranged on a line for a certain equation. If only two or three points among them are taken, there can be many curves satisfying these points. But if many points are taken there can be only a curve which
satisfies any of the points. On the other hand, if the number of terms are few the experimental or accidental error for each datum has much influence on the value of constant of the equation. Therefore the data of few experimental terms are not sufficient to examine the applicability of equations. The larger the number of terms the better.
(iii) Examination by ploting the curve of experimental result

It is an easy and very important method to examine the experimental data by plotting them before applying the equation to the data. The points on the coordinates for experimental result are generally on a smooth curve and if one or two special data are plotted distinctly out of the curve they are considered to be data with accidental error and therefore they are not to be taken in applying the equation.

If one takes all the data without selection in applying an equation it shows sometimes an apparently good application while the true fact is the contrary. Such mistaken proofs can be seen often among the preceding reports.
(iv) The nature of the equation to be examined and the natire of the experimental curve must be the same

The equation was sometimes examined for data without being considered the nature of the equation and experimental curve. By such an examination no perfectly applicable equation can be found. For instance, in the decomposition of starch the maximum hydrolyzable quantity that is obtained with amylase differs from that with hydrochloric acid. To the data obtained with amylase the monomolecular equation was sometimes applied by taking the quantity of glucose equivalent to the quantity of starch (obtained in the decomposition with hydrochloric acid) as the value of $a$ in the equation. But in such a case the maximum hydrolyzable quantity of the substrate taken that is obtained by the enzyme action must be taken as the value of $a$ (cf. page 168 ), and the percentage of the substrate decomposed must be calculated by taking that maximum quantity as the base. On the other hand, for instance the monomolecular equation, which passes through the original point was sometimes applied by some preceding investigators to data which did not pass the original point. In such a case the equation must be applied to such data that are obtained by subtracting the experimental value at the beginning from each experimental value as some other investigators did.
(B) In estimating the applicability of equations it is necessary to examine :

Proposition of T.N.n. Eouations in the Kinetics of Enzymes 163
(i) The uniformity of the values of the constant and the differcnce betzeeen experimenta! and calculated values

The applicabilities of two different equations have been very often compared with each other only by the uniformity of the values of the constant. But such a method only is inadequate to determine the better applicability; and the mean differences between experimental and calculated values or probable errors for both equations must be compared as already reported.
(ii) Is there or is there not a certain definite tendency in (a) the values of the constant or (b) the differences between cach pair of experimental and calculated values in the result obtained?

If the equation is perfectly applicable the positive or negative sign of the difference between the experimental and the calculated values must occur irregularly and the absolute sum of the positive differences must be about equal to that of the negative. Such a fact means to follow the principle of probability itself. Therefore if one observes "the increasing or decreasing tendency of the value of a constant ", or " such a tendency in the value of the difference between each pair of experimental and calculated values" or "such a tendency in the occurrence of the sign of the values of the difference," then one can not recognize the perfect application of the equation even though the degree of the tendency is slight.

## 4. Application of T. N. N. equations to published data

The applicability of T. N. N. equations to some data has been proven in this paper and in a previous report. ${ }^{(19)}$ Here the author is going to show collectively the results of the application of T. N. N. equations to data obtained by himself and to data obtained by preceding investigators with enzymes of various kinds. He takes data from as many reports as he can find. The author will not show or criticize all the theories in enzyme kinetics which have been proposed by preceding scholars. The several items which were mentioned under paragraph 3 are to be always kept in mind in the following examinations.

Lipase and esterase
A) Plant lipase

1) Castor bean lipase
(i) Data obtained by Nakajima in the decomposition of soy bean oil. T. N. N. I is satisfactory. ${ }^{(49)}$
(ii) Data obtained by Nicloux ${ }^{(53)}$ in the decomposition of cotton seed oil. The applicability of the monomolecular law was supported. The data taken for an example does not plot a smooth curve. To the data T. N. N. I is applied, which is better than the monomolecular law though it is not perfect as seen in Table XXX. This is due perhaps to the fact that the viscosity of each sample was not constant through all the time of decomposition. ${ }^{(48)}$
(iii) Data obtained by Willstätter and Waldschmidt-Leitz ${ }^{(88)}$ in the decomposition of olive oil. T.N.N.I is satisfactory. (Table XXXI).
(iv) Date obtained by Willstätter and Waldschmidt-Leitz ${ }^{(83)}$ in the decomposition of castor bean oil. T.N.N. I is satisfactory. (Table XXXII).
(v) Data obtained by $\mathrm{T}_{\mathrm{AyLOR}}{ }^{(71)}$ in the decomposition of triacetin. T. N. N. I is satisfactory. (Table XXXIII).

As examined above T. N. N. I is always satisfactory for data obtained in the decomposition of any substrate by castor bean lipase.

## 2) Papain lipase

(i) Data obtained by Nakajima in the decomposition of soy bean oil. T. N. N. II is satisfactory. ${ }^{(49)}$
(ii) Data obtained by Sandrerg and Brand ${ }^{(64)}$ in the decomposition of olive oil. T. N. N. II is satisfactory. (Table XXXIV and XXXV).

## 3) Lipase of fly amanita

Data obtained by Zellner. ${ }^{(86)}$ T.N.N. II seems satisfactory (Table XXXVI).
B) 1 nimal lipase

1) Lipase of stomach

Data obtained by Stade. ${ }^{(63)}$ The equation $K . F=\frac{F}{t} \log \frac{a}{a-x}-\frac{x}{t}$ was reported by Arrhenius ${ }^{(5)}$ to be satisfactory. This equation is unsatisfactory as shown in Table. XXXVII. T. N. N. I is always more satisfactory than T. N. N. II as shown in Table XXXVIII. T. N. N. I is not quite satisfactory, perhaps due to the fact that the data do not fall on a smooth curve.
2) Parcreas lipase
(i) Data obtained by Engel ${ }^{(19)}$ in the decomposition of egg-yolk. The Schütz law was accepted by Engel. The results given in Table XXXIX seem not proper and are not adequate for examining the applicability of equations. With such incomplete data the applicability of any equation cannot be determined.
(ii) Data obtained by Willstätter and Memmen ${ }^{(T 7)}$ in the decomposition of triacetin. The Schütz law was supported. As seen in Table XL, no perceptible difference of applicability can be seen between T. N. N. I and II.
(iii) Data obtained by Dietz $^{(16)}$ in the synthesis of ester. The reaction in the presence of little water was thought by Dietz to follow the equation $\frac{d x}{d t}=K(a-x)$. But, T.N. N. I seems to be best applicable as shown in Table XLI.
(iv) Data obtained by Dietz in the synthesis of ester in the presence of comparatively much water. The opposite kinds of reaction were considered by Dietz thus,

$$
\frac{d x}{d t}=k_{1}(a-x)-k_{2} x .
$$

At the equilibrium of reactions $\frac{d x}{d t}=0$. If the quantity of $x$ at the state of equilibrium be represented by $\varepsilon$ the following equations were obtained by Dietz:

$$
\begin{aligned}
& \frac{\mathrm{C}_{\mathrm{E}}}{\mathrm{C}_{\mathrm{S}}}=\frac{k_{1}}{k_{2}}=K=\frac{x}{a-x}=\frac{\varepsilon}{a-\varepsilon} \\
& k_{1}=\frac{1}{t} \frac{\varepsilon}{a} \ln \frac{\varepsilon}{\varepsilon-x} ; \quad k_{2}=\frac{1}{t} \frac{a-\varepsilon}{a} \ln \frac{\varepsilon}{\varepsilon-x}, \\
& k_{1}+k_{2}=\frac{1}{t} \ln \frac{\varepsilon}{\varepsilon-x} .
\end{aligned}
$$

To the data which were obtained by him with the solution of $6.5 \%$ water and 5.01 g of enzyme, T.N.N. I and II were applied as given in Tables XLII-XLIV. The result of application of T. N. N. I, omitting the fourth datum which is certainly out of a smooth curve, is given in Table XLIV. As seen in these tables T. N. N. I is well applicable to Dietz's data although it is not perfect.
3) Liver lipase
(i) Data obtained by Herzog ${ }^{(32)}$ in the decomposition of ethyl acetate. To Herzog's data T. N. N. I and II are almost equal in applicability as given in Table XLV. The best equation is to be determined by the examination of data of wide range of decomposition.
(ii) Data obtained by Kastle, Johnston and Elvolve ${ }^{(40)}$ in the decomposition of ethyl butyrate. They considered that their data followed the $1 \frac{1}{2}$ molecular equation. Their calculated result is given in Table XLVI where the data of the last column were found by the present author. He applied T. N. N. I and II to the data as given in Tables XLVII and XLVIII. The experimental curve seems to be not smooth and the data are not adequate for examining the applicability of equations. However T. N. N. II is considered to be satisfactory fundamentally.
4) Lipase of fatty tissue

Data obtained by Euler ${ }^{(20)}$ in the decomposition of ethyl butyrate as given in Table XLIX. To the data T. N. N. I seems satisfactory as shown in Table L.

## 5) Lipase of blood

(i) Data obtained by Rona and Ebsen. ${ }^{(63)}$ The condition of experiment is as follows: 60 cc . of saturated tributyrin solution +5 cc . of $\mathrm{H}_{2} \mathrm{O}+2 \mathrm{cc}$. of phosphate mixture $+\mathrm{I} \sim 2 \mathrm{cc}$. of rabbit blood of $\mathrm{I} / \mathrm{IO}$ concentration; determined by a staragmometer at $18^{\circ} \mathrm{C}$. The monomolecular equation was applied by the authors. The present author applied T. N. N. I and II to their data taking the value of $a-x$ at $t=0$ as the value of $a$ in the equations. T.N.N. I seems to be well applicable as seen in Tables LI and LII.
(ii) Data obtained by Pighini ${ }^{(57)}$ in the decomposition of monobutyrin by serum lipase of guinea pig. The best applicable equation cannot be determined as between T. N. N. I and II.

The author applied T. N. N. I and II to many published data obtained with various lipases. The best applicable equation has been determined for each lipase with few exceptions as given in Table LIII.

## Chlorophyllase

To the data obtained by Wilistätter and Stoll, ${ }^{(82)}$ T. N. N. II is satisfactory as shown in Table LIV.

Proposition of T.N.N. Equations in the Kinetics of Enzymes i67

## Lichenase

(i) Data obtained by Karrer, Joos and Staub. ${ }^{(39)}$ The condition was as follows: 0.4 g lichenin in 250 cc . of phosphate mixture; $P_{H}$ value $5.25 ; 36^{\circ} \mathrm{C}$. Two results followed T. N. N. II as given in Tables LV and LVI.
(ii) Data obtained by Pringsheim and Seifert. ${ }^{(61)}$ The third datum of this is out of a smooth curve as shown in Fig. I. Therefore the equations were applied to the result omitting the datum. T. N. N. II is satisfactory as given in Table LVII.

## Inulase

(i) Data obtained by Boselli ${ }^{(11)}$ under such conditions as 20 cc . of $4 \%$ inulin solution +10 cc . of buffer solution of $\mathrm{P}_{\mathrm{H}}$ value $3.8+10 \mathrm{cc}$. of $\mathrm{H}_{2} \mathrm{O}+40 \mathrm{cc}$. of enzyme solution; $37^{\circ} \mathrm{C}$. In Table LVIII $x$ is the quantity of fructose in mg and $a$ the maximum hydrolysable quantity. Boselli applied the moromolecular law which is distinctly not perfect. T. N. N. equations were applied to the data, taking 222 as the maximum quantity of decomposition. As seen in Table LIX, T. N. N. II seemed better but as the differences for the 7 th datum were specially large in both results the equations are again applied omitting this datum as seen in Table LX, where T. N. N. I is better applicable than II and the result of the application of T. N. N. II in Table LVIII is considered to be not true.
(ii) A result obtained by Pringsheim and Perewosky ${ }^{(60)}$ under such conditions as 20 cc . of $4 \%$ inulin solution +10 cc . of buffer solution of $\mathrm{P}_{\mathrm{H}}$ value $3.8+40 \mathrm{cc}$. of enzyme solution A. Similar to the previous example, the applicability of T. N. N. II is not true. As seen in Table LXI, T. N. N. I is better than II although the applicability is not perfect.

For the data obtained with enzyme solution B, T. N. N. I is also better.

Inulase seems to follow T. N. N. I.

## Cellobiase

Data obtained by Pringsheim and Leibowirz ${ }^{(59)}$ under such conditions as, $\mathrm{P}_{\mathrm{HI}}$ value $5 ; 37^{\circ} \mathrm{C}$. This result follows T. N. N. II as given in Table LXII. To another result of the same authors the applicability of both T. N. N. I and II is low, but as the data of the result are only 3 further examination cannot be done.

1) Taka-diastase

## Amylase

Data obtained by Philoche. ${ }^{\text {(56) }}$ For the result obtained with $1 \%$ starch, T. N. N. I is better applicable than II, as seen in Table LXIII. For the result obtained with $2 \%$ starch the better applicability cannot be determined certainly between T. N. N. I and II, but the former seems to be better, as seen in Tables LXIV and LXV. For the result obtained with $3 \%$ starch T.N.N. I seems also better than II, as seen in Table LXVI.

From the examination above given three results obtained by Philoche with Taka-diastase can be recognized to follow T. N. N. I.

## 2) Malt-diastase

(i) Data obtained by Henri ${ }^{(31)}$ with $3 \%$ starch solution at 25 C . T. N. N. I seems to be satisfactory, as seen in Table LXVII.
(ii) Data obtained by Brown and Glendinning. ${ }^{(13)}$ The authors applied the equation $K=\frac{1}{t} \ln \frac{a+x}{a-x}$ to their data. It seems very satisfactory but the applicability cannot be determined only from ascertaining the uniformity of the values of the constant. The experimental result seems to follow T. N. N. I as seen in Table LXVIII, although it is not perfect.
(iii) Data obtained by Sherman and Walker. ${ }^{(68)}$ The authors applied the monomolecular law to their data, taking the value of the quantity of glucosc equivalent to the quantity of starch taken as the value of $a$ in the equation. The applicability is very low. The present author considers that such a method of application is not proper. In the decomposition by amylase there is a certain maximum hydrolysable quantity according to the experimental condition, the value of which must be taken as the value of $a$. The value of that maximum quantity is uncertain in their report. Therefore the best applicable equation cannot be determined for their results.

## 3) Pancreas amylase

Data obtained by Henri. ${ }^{(31)}$ He applied the monomolecular equation. T. N. N. I is almost perfect as seen in Table LXIX. As the value of $k^{\prime}$ is near I the monomolecular equation is equally good.
4) Liver amylase

Data obtained by Holmbergh ${ }^{(36)}$ with starch and glycogen. They follow T. N. N. II as seen in Table LXX.

The author has examined the applicability of equations to published data obtained with amylase. The best equation for each amylase is shown in the recapitulation in Table LXXI.

## Maltase

(i) A result obtained by Willstätter, Oppenheimer and SteiBelt ${ }^{(80)}$ in the decomposition of maltase with the extract of yeast of Löwenbräu. The applicability of T. N. N. I is perfect, as given in Table LXXII.
(ii) Data obtained by Philoche ${ }^{56)}$ in the decomposition of maltose with Taka-diastase. He applied the equation $K=\frac{a}{t}\left(\frac{2 x}{a}+\ln \frac{a}{a-x}\right)$ to his data. The equation was considered better than the monomolecular equation. The values of $K$ are comparatively near one another and the equation seems to be satisfactory, but the point is uncertain. T. N. N. I and II equations were applied as given in Table LXXIII. The equations were applied further to data without 4th and 6th data or without 3 rd and 5 th data but the better applicable equation could not be determined. The two equations do not seem to be satisfactory.
(iii) Data obtained by Willstätter and Steibelt ${ }^{(81)}$ in the decomposition of $\alpha$-methyl glucoside. The results of application of T. N. N. I and II are given in Table LXXIV. T. N. N. II is almost satisfactory.
(iv) Data obtained by Willstätter and Oppenheimer ${ }^{(78)}$ in the decomposition of $\alpha$-ethyl glucoside with the yeast of Löwenbräu. As seen in Table LXXV, T. N. N. I is satisfactory.
(v) Data obtained by Willstätter and Oppenheimer in the decomposition of a-phenyl glucoside. As given in Table LXXVI, T.N. N. II is surely better than I.

The best applicable equations for data obtained with maltose from various sources are summarized in Table LXXVII.

## Emulsin

(i) Data obtained by HerzoG ${ }^{(34)}$ in the docomposition of salicin. Herzog considered that the equation $K_{4}=K_{2}\left(\frac{K_{2}}{K_{1}}-a\right)$ held true where
$\mathrm{K}_{2} \cdot a=\mathrm{K}_{1} . \mathrm{O} .6$ and $\mathrm{K}_{1}$ is the constant of monomolecular law. T. N. N. I is satisfactory as seen in Table LXXVIII.
(ii) Data obtained by Willstätter and Oppenheimer ${ }^{(78)}$ in the decomposition of arbutin. Cf. Table LXXIX.
(iii) A result obtained by Willstätter and Openheimer ${ }^{(78)}$ in the decomposition of $\beta$-methyl glucoside. Cf. Table LXXX.
(iv) Data obtained by Willstätter and Oppenheimer ${ }^{(78)}$ in the decomposition of $\beta$-phenyl glucoside. Cf. Table LXXXI.
(v) Data obtained by Willstätter and Oppenheimer ${ }^{(78)}$ in the decomposition of helicin. Cf. Table LXXXII.
(vi) Data obtained by Willstätter and Csányi ${ }^{(55)}$ in the decomposition of raffinose. Cf. Table LXXXIII.

For the data given under (ii)-(vi) T. N. N. I is satisfactory. As the value of $k^{\prime}$ is near $I$ in all cases the monomolecular law shows almost the same applicability.

As examined above T. N. N. I is satisfactory for emulsin.

## Invertase

(i) Data obtained by Michaelis and Menten ${ }^{(45)}$ follows T. N. N. I as given in Table VI.
(ii) Data obtained by Nelson and Hitchcock. ${ }^{\text {(51) }}$ They obtained an experimental equation,

$$
t=222.9 \log \frac{100}{100-p}+0.5890 p-0.001974 p^{2}-0.00002043 \not p^{3}
$$

where $p$ denotes the percentage of substrate decomposed. T. N. N. I was applied as given in Table LXXXIV. The equation is not quite satisfactory for Nelson and Hitchcock's result, but it can be said to be applicable to a certain extent.
(iii) Data obtained by Euler and Kullberg. ${ }^{(24)^{*}}$ They obtained an enzyme solution by treating fresh yeast with $0.67 \% \mathrm{KH}_{2} \mathrm{PO}_{4}$ solution. To their data T. N. N. I is well applicable as seen in Table LXXXV.

## Raffinase

(i) Data obtained by Willsttäter and Kuhn. ${ }^{(76)}$ The decomposition was considered to follow the monomolecular law. T. N. N. I is almost satisfactory as seen in Table LXXXVI.
(ii) Data obtained by Colin and Chaudan. ${ }^{(44)}$ T. N. N. I is almost satisfactory as seen in Table LXXXVII.

## Lactase

i) Data obtained by Willstätter and Oppenheimer. ${ }^{(78)}$ They decomposed lactose of $5 \%$ solution with the neutral extract of saccharomyces fragilis. $P_{H}$ value, 7.0 ; decomposed at $30^{\circ} \mathrm{C}$. T.N.N. I is satisfactory as seen in Table LXXXVIII.
2) Data obtained by Armstrong. ${ }^{(3)}$
(i) He applied the Schürz law. T. N. N. I is not satisfactory for all the data but it is satisfactory for the data without the last datum as given in Table LXXXIX.
(ii) Data obtained by using a solution of 100 cc . which contained 0.4 g of emulsin. The monomolecular law was applied. The value of the constant fell with the progress of decomposition. T.N.N. I is satisfactory as seen in Table XC.
(iii) Data obtained by using a solution of 100 cc . which contained 0.1 g of emulsin. T.N.N. I is much better than the monomolecular law as seen in Table XCI.
3) Data obtained by WilistÄtter and Csányi. ${ }^{(70)}$ The conditions were : $\mathbf{2 0} \mathbf{c c}$. of $0.7 \%$ lactose +50 mg of emulsin ; at the optimum $\mathrm{P}_{\mathrm{H}}$ value of 4.4 ; decomposed at $30^{\circ} \mathrm{C}$. T. N. N. I is almost satisfactory and is better than II as seen in Table XCII.

## Mannase

Data obtained by Mivake $^{(46)}$ with mannase of aspergillus niger. T. N. N. I is always satisfactory as seen in Table XCIII.

## Tannase

Freudenberg ${ }^{(27)}$ applied the monomolecular law to his data obtained in the decomposition by tannase. The value of $K$ decreased with the increase of the decomposition time, which he attributed to the influence of the increasing quantity of acid. Most of the results of Freudenberg are not adequate to examine the applicability of equations. To some of his results T. N. N. I and II were applied. T. N. N. I is satisfactory within a certain degree of decomposition as seen in Table XCIV.

## Pepsin

1) Data obtained by Nakamura ${ }^{(50)}$ with proteins of barleys. T. N. N. II is satisfactory.
2) Data obtained by NaKajima ${ }^{(49)}$ with glycinin. T. N. N. II is satisfactory.
3) Data obtained by Matsuyama and Nakamura ${ }^{(43)}$ in the decomposition of egg-white. T. N. N. II is satisfactory as seen in Table XCV.
4) Data obtained by Rona and Kleinmann ${ }^{(64)}$ in the decomposition of serum albumin at $40^{\circ} \mathrm{C}$. For their many results the author examined the applicability of T. N. N. I and II. Some of the results are shown in Table XCVI. According to the group of data, either T. N. N. I or T. N. N. II is apparently more applicable than the other. As seen in the table, T. N. N. I is sometimes better than II, but II is considered to be truly applicable.

The data obtained in the decomposition by pepsin have been proved to follow T. N. N. II.

## Trypsin

1) Data obtained by Nakajima in the decomposition of normal and denatured glycinins. T.N.N. I was always better applicable than II. ${ }^{(49)}$
2) Data obtained by Rona and Kleinmann. ${ }^{\text {(61) }}$ They gave about a hundred results in their paper, from which several were taken at random and T. N. N. equations were applied to them. Some of the results are given in Table XCVII. The result given in Table XCVII (v), where T. N. N. II is better than I, is exceptional. But the difference of applicability is very small. T. N. N. II seems to have shown an apparently good application.
3) A result obtained by Bayliss ${ }^{(10)}$ in the decomposition of sodium caseinate. Arrhenius applied the equation, $a(\log a-\log x)-(a-x)=K t$, to Bayliss's data as shown in Table XCVIII in which a denotes the degree of conductivity. As the value of $a$ in applying T. N. N. equations is uncertain, they cannot be applied.

## Papain

Data obtained by Nakajima in the decomposition of the normal and denatured glycinins. T. N. N. II was satisfactory. ${ }^{(49)}$

## Protease

1) Data obtained by Oshima ${ }^{(65)}$ with yeast protease. He applied the Schütz law to his data and considered it to be more satisfactory than the monomolecular law. For the data obtained with peptone T. N. N. II is satisfactory, while for the result obtained with casein T. N. N. I is satisfactory, as seen in Table XCIX.
2) Data obtained by $\mathrm{WeIs}^{(73)}$ in the decomposition of glutin with protease of germinating barley. T. N. N. II is satisfactory as seen in Table C. But as the range of decomposition is very narrow further examination is needed.
3) Data obtained by Dernby ${ }^{(15)}$ in the auto-digestion of yeast with its endotryptase. Dernby compared the applicabilities of the Schütz law, Arrhenius's equation, $K_{A}=\frac{1}{t} a \cdot \ln \frac{a}{a-x}-x$, Henri's equation, $K_{H}=\frac{1}{t} \ln \frac{a+x}{a-x}$ and his own equation, $K_{n}=\frac{1}{\sqrt{t}} \ln \frac{a+x}{a-x}$. The last equation was considered the best. As the value of the experimental result for time 0 was 8 , the value $100-8$, and the value of $x-8$ must be taken respectively as the value of $a$ and the value of $x$ in applying such equations as above shown. Dernby's method of application of equations is, in the present author's opinion quite mistaken. In most cases T.N. N. I is better than II as seen in Table CI and CII.

## Peptidase

1) Data obtained by Abderhalden and Fodor ${ }^{(1)}$ in the decomposition of glycyl-1-leucin by yeast extract

The results of application of T. N. N. I and II, taking 0.0625 as the value of $a$, are given in Table CIII, where the best applicable equation cannot be determined. However, as the value of the probable error even for the equation of lower applicability is small for each experimental result, T. N. N. I or II only is considered to be fundamentally applicable for Abderhalden and Fodor's data.
2) Data obtained by EuLER ${ }^{(22)}$ in the decomposition of glycylglycin with erepsin

As in the previous case, the best applicable equation cannot be determined, as seen in Table CIV.

## Arginase

1) Data obtained by Gross ${ }^{(29)}$ follows T. N. N. II. (Cf. Table I.)
2) Data obtained by Edlbacher and Simons ${ }^{(18)}$

The results of application of T. N. N. equations are shown in Table CV, where T. N. N. II is always better applicable than I, though it is not perfect.

## Urease

Armstrong ${ }^{(4)}$ reported that the decomposition by urease did not follow the monomolecular equation. Van Slyke and Cullen ${ }^{(72)}$ proposed an equation, $E t=\frac{1}{c} \log \frac{a}{a-x}+\frac{x}{d}$. BaRENDRECHT's empirical equation is $m=\frac{1}{t}\left[0.0176 \log \frac{1}{1-y}+0.02 y\right]$ which is included in VAN Slyke's equation. Lövgren ${ }^{(41)}$ examined the equation of Van Slyke and concluded that it was not satisfactory for their special data.

1) Data obtained by Barendrecht ${ }^{(9)}$

A Barendrecht's result given in Table CXVI has many terms and plots a very smooth curve and the range of the decomposition is wide. Therefore it seems to be satisfactory for exemining the applicability of an equation. For the result, the applicability of T. N. N. II and III is not satisfactory. T. N. N. I is much better than T. N. N. II or III although it is not very satisfactory. The experimental result is very peculiar, in spite of the very smooth curve of it, for the quantity obtained in the decomposition for 5 th 20 mins. is much larger than that for 4 th 20 mins., which shows that his result is not accurate. The applicability of T. N. N. I to the data without the 4 th and the last two data is little better than that to the whole data as shown in Table CXVI. T. N. N. I seems to be fundamentally applicable.
2) Data obtained by WESTER ${ }^{(74)}$

The data of each group of Wester's results are too few to determine the applicability of an equation but T. N. N. equations were applied for trial. T. N. N. I is better than II as seen in Table CVII.

As examined above T. N. N. I seems to be satisfactory for data obtained with urease.

## Asparaginase

Data obtained by Geddes and Hunter ${ }^{(28)}$ with yeast asparaginase.

Proposition of T.N.N. Equations in the Kinetics of Enzymes 175
T. N. N. I seems better applicable than II within $50 \%$ decomposition as seen in Table CVIII.

## Phosphatase

1) Data obtained by Euler and Kullberg ${ }^{(84)}$

Their experimental conditions were as follows:
The solution (of 300 cc . of $23 \%$ sucrose +50 g of dry yeast) was mixed for $3 \frac{1}{2}$ hrs.; 40 cc . of filtrate +40 cc . of $2 \%$ neutral $\mathrm{NaH}_{2} \mathrm{PO}_{4}$ solution.

The experimental terms are few. T.N.N. II is better than I or the monomolecular law, as shown in Table CIX.

A similar result of application was obtained for other of their data obtained with glucose instead of sucrose.
2) Data obtained by Djenab and Neuberg ${ }^{(17)}$

Their experimental conditions were as follows:-
20 g of Na -saccharophosphate +20 g of yeast +400 cc . of $\mathrm{H}_{2} \mathrm{O}+$ 20 cc . of toluene; decomposed at $30^{\circ} \mathrm{C} . ; \mathrm{P}_{2} \mathrm{O}_{5}$ was determined with magnesium mixture. T. N. N. II is better applicable than I though it is not satisfactory as seen in Table CX.
3) Data obtained by Nemec ${ }^{(59)}$

Glycerophosphate was decomposed by phosphatase of yellow soy bean under such conditions as 20 g of seed in 40 cc . of $1 \%$ sodium glycerophosphate + rocc. of toluene. Nemec applied the Schütz law to his data and considered it to be satisfactory for the data obtained at the beginning of decomposition. T. N. N. II is better than I as seen in Table CXI.

## Mutase

Euler and Brunius obtained data with mutase. ${ }^{(23)}$
(i) Data obtained in the absence of co-enzyme. No marked difference of applicability can be seen between T. N. N. I and II, as shown in Table CXII (i).
(ii) Data obtained in the presence of co-enzyme. T.N.N. I is better applicable than II as seen in Table CXII (ii).
(iii). Enzyme solution was before treated with acetic acid. Not all the data shown in Table CXII (iii) are proper to apply the equation to, which is clearly shown by plotting the data. T. N. N. I seems better than II for the data without the 3rd datum as seen in the table.

To determine the best equation for data obtained with mutase, further examination is needed. But T. N. N. I seems to be satisfactory.

## Peroxidase

I) Data obtained by Willstätter and Stoll ${ }^{(82)}$ with vegetable peroxidase

Pyrogallol was decomposed to purpurogallic acid. The application of the monomolecular law to the data was supported as true by the authors. T. N. N. I is better than II as seen in Table CXIII.
2) Data obtained by Bansi ${ }^{(8)}$ with extract of horse radish

The bimolecular equation was taken to be well applicable. The values of probable error for both T. N. N. I and II are large and a satisfactory equation cannot be determined, as shown in Table CXIV.

## Catalase

1) Yeast catalse

Data obtained by Issajew ${ }^{(37)}$ have been examined as follows:
(i) T. N. N. I is satisfactory as already given in Table IX.
(ii) T. N. N. I is satisfactory as already given in Table X.

## 2) Catalase of shaggy boletus

Data obtained by Eulek ${ }^{(20)}$
(i) Data obtained with 3 cc . of enzyme solution. T. N. N. II is satisfactory as already given in Table XII.
(ii) Data obtained with 4 cc . of enzyme solution. T. N. N. II is satisfactory as shown in Table CXV (i).
(iii) Data obtained with 5 cc . of enzyme solution. The results of application of T. N. N. II are shown in Table CXV (ii). T. N. N. II is satisfactory.

As examined above T. N. N. II is always satisfactory for Euler's data.
3) Liver catalse

Data obtained by Rona and Damboviceanu ${ }^{(62)}$ ?
(i) Data obtained with the water solution of enzyme. The $1 \frac{1}{2}$ molecular equation was applied by the authors. T. N. N. II is satis-
factory as shown in Tables XXVIII and XXIX.
(ii) Data obtained with the enzyme solution of 5 cc . of 0.154 mol . NaCl . Rona considered that the decomposition was slow because of the retarding action caused by NaCl , as if only a little quantity of enzyme had been used, and he considered that the bimolecular equation was satisfactory, as shown in Table CXVI. As often shown, the value of $K$ of this equation is apparently uniform, but the proof is very incomplete. Although T. N. N. II is better than I for all the data, the probable error is not small. As the point for the third term seems to be out of a smooth curve and the number of experimental terms are few, the data themselves are not proper for examining the applicability of equations.
(iii) Data obtained with 5 cc . of 0.15 mol . of $\mathrm{NaCl}, 0.025 \mathrm{~mol}$. of $\mathrm{KCl}, 0.0018 \mathrm{~mol}$. of $\mathrm{KCl}, 0.0018 \mathrm{~mol}$. of $\mathrm{CaCl}_{2}$ and 0.0011 mol . of $\mathrm{NaHCO}_{3}$. The retarding action of NaCl was considered to be prevented by the presence of $\mathrm{NaHCO}_{3}$ and the decomposition was considered to follow the $1 \frac{1}{2}$ molecular equation. T. N. N. II is very satisfactory as shown in Table CXVII.

Two of the three results above taken follow certainly T. N. N. II.

## 4) Blood catalase

(i) Data obtained by Senter. ${ }^{(66)}$ T. N. N. I is satisfactory as shown in Table CXVIII and as the value of $k^{\prime}$ is always near I the monomolecular equation is also about equally well applicable.
(ii) Data obtained by Yamazaki. ${ }^{\text {(85) }}$ Yamazaki's study has been previously introduced in this paper. In the following example $\mathrm{E}_{0}$ denotes the quantity of enzyme and $\mathrm{C}_{0}$ the quantity of substrate taken. T.N.N. I is always satisfactory, as shown in Table CXIX. The value of $k^{\prime}$ of Yamazaki's equation decreases with the progress of decomposition and the result of the application of his equation is, more or less, unsatisfactory, which Yamazaki himself recognized in his report.
(iii) Data obtained by Maximowitsch and Awtonomova. ${ }^{(41)}$ Their theory and equation has been already introduced in this paper. The range of decomposition in their experimental data is very narrow for examining the applicability of equations and the number of terms for calculating the mean value of $D$ in Maximowirsch's equation is quite uncertain for a certain number of experimental terms. These have already been pointed out by the present author. For trials T. N. N. was applied to
their data to examine the applicability. The results obtained in applying T. N. N. I are given in Table CXX.
5) Catalase of soy bean

Results obtained by Yamazaki. The meaning of $\mathrm{E}_{0}$ and $\mathrm{C}_{0}$ was shown on page 158 . The sign of the difference obtained by Yamazaki occurs not irregularly. Most of the values of differences, 4 , in one calculated result are positive or negative, which itself shows the imperfection of Yamazaki's equation. T. N. N. I is not always satisfactory but it seems to be applicable.

From the examination of the equations above shown it is seen that the highest applicable equation for catalase of yeast and blood is $T$. N. N. I and that for catalase of liver and shaggy boletus T. N. N. II.

## Zymase

1) Data obtained by Aberson ${ }^{(2)}$

Aberson considered the equation $\frac{1}{t} \log \frac{a+x}{a-x}=K$ to be satisfactory for his data. The result of application of T. N. N. I is shown in Table CXXI. The better equation of these two cannot be here determined.
2) Data obtained by Euler ${ }^{(21)}$
T. N. N. I seems to be satisfactory as shown in Table CXXII.
3) Data obtained by Herzog ${ }^{(32)}$

Herzog applied $\frac{1}{t} \log \frac{a}{a-x}=K_{1}$ and Aberson's equation, $\frac{1}{t} \log$ $\frac{a+x}{a-x}=K_{A}$ to his data. To compare the applicability of these equations with that of T.N.N.I, the present author applied $\frac{1}{t^{\prime}} \log \frac{a+x}{a-x}=K$ instead of $\frac{1}{t} \frac{a+x}{a-x}=K_{A}$ and T.N.N.I. The probable error for the latter equation is always smaller than that of the former as seen in Table CXXIII.

## 5. Recapitulation of results of application of T.N.N. equations

From the results of application of T. N. N. I and II to the author's data and to the principal published data of as many reports as he could find, the kind of enzyme and substrate, and the best applicable equa-
tion are extracted and tabulated in Table CXXIV. For some kinds of enzymes further examination is necessary or some corrections may be possible in the determination of applicable equations because the data used for examination are not all adequate.

## Decomposition, taking the relative quantity of enzyme as a variable

In this part, equations applicable to data obtained in decomposition taking the relative quantity of enzyme as a variable will be studied.

## 1. Examination of the equation $\frac{\boldsymbol{x}}{\boldsymbol{E}}=\boldsymbol{K}$

The principal equations expressing the rate of decomposition taking the relative quantity of enzyme as a variable have once been reviewed in the author's report, " Refutation of the Schü̈tz law and its analogous equations in the kinetics of enzymes. ${ }^{(48),}$, In this report the Sснüтz law $\frac{x}{\sqrt{E}}=K$ was accepted by the present author for data obtained only with dilute pepsin. The reexamination of this equation will be made in the next paragraph. The cases of application of other equations have been few, except the equation $\frac{x}{E}=K^{*}$ (or $\frac{x}{e}=K$ ) which has been often applied and considered to be well applicable. Therefore only this equation will be hereafter examined. Although it is better than any other equation it is only comparatively so. To the writer the equation is quite unsatisfactory, which can easily be known if the items given under paragraph 3 on page 161 are considered. The curves of experimental results obtained in decomposition taking the relative quantity of enzymes as a variable must pass through zero point and $x \rightarrow a$ if $\lim _{\mathrm{E} \rightarrow \infty}$. The nature of the curve is quite the same as that obtained in decomposition taking time as a variable. Therefore the writer is going to modify the T. N. N. equations. Substitute $E^{k^{\prime}}$ for $t^{t^{c}}$ in T. N. N. I and II, and the following equations are obtained:

$$
\begin{aligned}
& \frac{1}{E^{k^{\prime}}} \log \frac{a}{a-x}=K, \\
& \frac{1}{E^{k^{\prime}}} \frac{x}{a(a-x)}=K .
\end{aligned}
$$

In these equations $E$ denotes the quantity of enzyme, $x$ the quantity
of substrate decomposed and $a$ the quantity of substrate taken or the quantity in ultimate decomposition. These equations are mathematically quite the same as the T. N. N. equations respectively. For the sake of convenience the equations above given will be denoted by T. N. N. (E) I and T. N. N. (E) II or merely (E) I and (E) II. These are usually satisfactory for experimental data as will be given later. In the results of application of the equation $\frac{x}{E}=K$ in original papers, only the values of $K$ are usually given. In the following examination the author will give the calculated value and the difference between the calculated and experimental values of the equation to compare the applicability with that of another equation.

## Lipase

## Cartor beau lipase

(i) Data obtained by Nicloux. ${ }^{(53)}$ (E) I is satisfactory while the value of the total differences for the equation $\frac{x}{E}=K$ is due almost to negative quantity, and the equation is not satisfactory as seen in Table CXXV.
(ii) Data obtained by Jalander ${ }^{(38)}$ with cotton seed oil at $22^{\circ} \mathrm{C}$. Within 52.77-4.64 percent decomposition the same defects of the equation $\frac{x}{E}=K$ as seen for the previous example are observed. The calculated results are given in Table CXXVI.

## Lactase

Data obtained by Armstrong ${ }^{(3)}$
The number of experimental data obtained by Armstrong are few, but for trial the comparison of the applicabilities of equations is made with calculated results as given in Table CXXVII. No marked difference of applicability between (E) I and (E) II can be observed but the defect of $\frac{x}{E}=K$ is clearly seen.

The defects of $\frac{x}{E}=K$ as shown for the above examples have been the same for any other examples. On the other hand T.N.N. (E) equations seem always to be satisfactory.

## 2. Reexamination of the Schütz law for data obtained with dilute peptic solution

The Schütz law, $\frac{x}{\sqrt{E}}=K$, has once been accepted by the present author only for data obtained with dilute pepsin. But as will be later shown T. N. N. (E) I is always well applicable to data obtained with either dilute or concentrated pepsin. It is necessary to compare the applicabilities of $\frac{x}{\sqrt{E}}=K$ and T. N. N. (E) I. The concentration of pepsin in J. Schütz's idea for the E. Schütz law does not mean the concentration of numerical expression. Therefore the present author will reexamine the law with examples for which it was accepted to be well applicable by preceding investigators. The data of a result which have the widest range of $x$ and $E$ in the original paper of E . Sснӥтz are first taken. As seen in Table CXXVIII each difference is comparatively small and the total positive quantity is about equal to the negative, though the distribution of the sign (positive or negative) is not satisfactory. But the present author found that the values of K calculated by Sснӥтz were mistaken. From the values of $E$ and $x$ the values of $K$ in correction and the difference between the experimental and calculated values of $x$ for different ranges of decomposition are found and shown in Table CXXIX. In this table the positive quantity is much larger than the negative and the distribution of both signs of difference is also not satisfactory. The point for the first datum is surely on a smooth experimental curve and if the theory of J. Schütz for the dilute pepsin that E. Schürz's law is true for data obtained with dilute peptic solution is true, the datum of the smaller percentage is the more important for maintaining the high applicability of the law. Yet the result of application obtained by omitting the first datum is apparently more satisfactory than that for all the data. E. Sснütz showed the total values of the experimental and calculated values respectively in each result of application. But such a comparison has no meaning or reason in evaluating his equation. As the maximum hydrolyzable quantity of the substrate taken is uncertain, T. N. N. (E) equations cannot be applied to his data. The other two examples given in Schütz's original paper are shown in Table CXXX. The first one is of data of a narrow range of decomposition and the second is of very few data. To examine the applicability of an equation neither of
the two results is adequate (cf. paragraph 3 on page 158 ). From the above examination the Schütz law $\frac{x}{\sqrt{E}}=K$ seems not to be satisfactory even for his own data.

Arrhenius applied his equation, $F . K_{A}=\frac{a}{t} 1 n \frac{a}{a-x}-\frac{x}{t}$, to one of J. Schürz's results. He wrote that it was better applicable than $\frac{x}{\sqrt{E}}=K$. The result of application of (E) I is given for comparison in Table CXXXI. To ascertain whether the applicability of Arrhenius's equation is true or apparent, much more examination with many data is necessary. There can scarcely be found any available data to which T.N.N. (E) I may be applied to compare the applicability with that of $\frac{x}{\sqrt{E}}=K$, because the value of $a$ is uncertain. Many experimental data and the results of application of $\frac{x}{\sqrt{E}}=K$ are given in Schütz and Huppert's paper. For these examples the same defects of $\frac{x}{\sqrt{E}}=K$ as already pointed out by the present author can be shown. Their results are not suitable for studying the applicability of equations. As the value of $a$ is uncertain or the terms of the experimental result are few, T.N.N. (E) cannot be applied to their data. The author accepted previously J. Schütz's theoretical explanation of the E. Schütz law. However his theory was deduced only from the inference and the experimental result is never satisfied by it. Now the present author rejects the Schütz law $\frac{x}{\sqrt{E}}=K$ for data obtained even with dilute pepsin.

## 3. Results of application of T. N. N. (E) equations to published data

The author applied T. N. N. (E) I and II to his data and to data obtained by the principal preceding investigators. He utilized as many reports as he could. The results will be given below.

## Lipase

## 1) Castor bean lipase

(i) Data obtained by Nakajima with soy bean oil. (E) I is satisfactory. ${ }^{(99)}$

Proposition of T.N.N. Equations in the Kinetics of Enzymes 183
(ii) Data obtained by Nicloux ${ }^{(53)}$ with olive oil. (E) I is satisfactory as shown on page 180 .
(iii) Data obtained by Jalander ${ }^{(38)}$ with cotton seed oil. (E) I is satisfactory as shown on page 180 .
2) Papain lipase
(i) Data obtained by Nakajima. T. N. N. (E) II is satisfactory. ${ }^{(49)}$
(ii) Data obtained by Sandberg and Brand. ${ }^{\text {(65) }}$ T. N. N. (E) II seems to be satisfactory as seen in Table CXXXII.
3) Pancreas lipase
(i) The applicabily of T.N.N. (E) equations was examined for a group of data obtained by Engel with egg-yolk and for that obtained by Willstätter, Waldschmidt-Leitz and Memmen. The best applicable equation was not constant to the whole data and limitted data of both authors.
(ii) Data obtained by Willstätter, Waldschmidt-Leitz and Memmen with olive oil. In this case the best equation cannot be determined as between (E) I and II as seen in Table CXXXIII.

For data obtained by pancrease lipase both (E) I and II are almost satisfactory but the better equation cannot be here determined as between (E) I and II.

## 4) Liver lipase

(i) Data obtained by Kastle and Loevenhart ${ }^{(41)}$ in the decomposition of ethyl butyrate by swine liver enzyme. (E) I is satisfactory as seen in Table CXXXIV.
(ii) Data obtained by Schmidt ${ }^{(67)}$ with morphine glycollic acid ester. (E) I is satisfactory as seen in Table CXXXV.

As above examined, to the data of the two results (E) I is well applicable.
5) Data obtained by STADE ${ }^{(69)}$ in the decomposition of egg-yolk

Satade applied the equation $x=\sqrt{F}$. $t$ where $F$ denoted the quantity of enzyme, $t$ decomposition-time and $x$ the quantity of substrate decomposed. The present author calculated the differences between the experimental and calculated values for his equation. All the differences are negative quantity as shown in Table CXXXVI, which shows the defect of the epuation. Neither T.N.N. I nor II is satisfactory, nor is the
better equation constant. This is because the experimental result may not have been accurate or the maximum hydrolyzable quantity may not have been 100 .

## Amylase

Data obtained by Oshima ${ }^{(55)}$ in the decomposition of soluble starch by enzyme solution prepared from Koji-kin. In applying T. N. N. (E) equations the value of glucose equivalent to the quantity of substrate was taken as the value of $a$.
(i) Data obtained in the decomposition for 20 mins.
T. N. N. (E) I and II are quite unsatisfactory as seen in Table CXXXVII. Oshima made it clear that the maximum hydrolyzable quantity obtained by the enzyme was far less than the quantity of the equivalent glucose. In a test 120 mg of glucose and not more were obtained with $2 \%$ enzyme solution. For trial 120 is taken as the value of $a$, yet the T. N. N. (E) equations are quite unsatisfactory as seen in Table CLXXXVIII. T. N. N. (E) III is also not satisfactory.
(ii) Data obtained in the decomposition for 1 hour

In the results of application taking 154 or 120 as the value of $a$, T. N. N. (E) I and II are also unsatisfactory as seen in Table CXXXIX.

For the data of other results T. N. N. (E) I, II and III were also unsatisfactory. In the decomposition by amylase there can be no satisfactory equation for the data obtained by taking the relative quantity of enzyme as a variable, even though they are plotted on a smooth curve, because the maximum hydrolyzable quantity varies with the quantity of the enzyme, i.e. the value of $a$ is not constant. (cf. page 162, (iv)).

## Lichenase

Data obtained by Pringsheim and Baur ${ }^{(68)}$
(i) Data obtained with purified lichenin. T. N. N. (E) II is satisfactory as shown in Table CXL.
(ii) Data obtained with ordinary lichenin. One of the results of application is shown in Table CXLI, where (E) II is better than (E) I though it is not at all satisfactory.

## Tannase

Data obtained by Freudenberg and Vollbrechi ${ }^{(27)}$ at $23^{\circ} \mathrm{C}$. for 24 hours decomposition. The results of application of T.N.N. (E) II for all the data or for data of $E: 0.01 \sim 0.08$ show that the equation is

Proposition of T.N.N. Equations in the Kinetics of Enzymes 185
better than (E) I, but as only the 4th datum is plotted out of a smooth curve the author compares the two equations for data, omitting that datum where ( E ) I is surely better than ( E ) II as shown in Table CXLII.

## Lactase

Data obtained by Armstrong. The better equation could not be determined, as already given in Table CXXVII.

## Pepsin

I. Data obtained by Nakajima in the decomposition of normal and denatured glycinis. (E) I was satisfactory. ${ }^{(49)}$
2. Data obtained by Matsuyama and Nakamura ${ }^{(43)}$ in the decomposition of egg-white in the solution of $\mathrm{P}_{\mathrm{H}}$ value 1.75 at $37^{\circ} \mathrm{C}$. by Merck's pepsin of two kinds, A and B. T. N. N. (E) I was always satisfactory. Some of the calculated results are given in Table CXLIII.

## Pancreatin

Data obtained by Nakajima in the decomposition of normal and denatured glycinins. (E) I was satisfactory. ${ }^{(49)}$

## Protease

(i) Data obtained by Oshima ${ }^{(55)}$ in the decomposition of Witte's peptone with aspergillus protease. T. N. N. II is better than I as seen in Table CXLIV.
(ii) Data obtained by Oshma ${ }^{(55)}$ in the decomposition of casein with aspergillus protease. The T.N.N. (E) II seems to be satisfactory.

## Polypeptidase

Data obtained by Grossmann and Dyckerhoff ${ }^{(30)}$ in the decomposition of d-l-leucyl-glycyl-glycin. (E) I is better applicable than II as seen in Table CXLV.

## Asparaginase

Data obtained by Geddes and Hunter ${ }^{(28)}$ with asparaginase of yeast. (E) I seems to be applicable to their data as seen in Table CXLVI.

## Emulsin

Data obtained by Tammann ${ }^{(70)}$ in the decomposition of salicin.
(i) Salicin of $3,007 \%$ solution was decomposed for 24 hours at $0^{\circ} \mathrm{C}$. More than $66 \%$ of salicin remained undecomposed even though more of the enzyme was used. 66 was taken as the value of $a$ in applying (E) I and II. The better applicable equation cannot be determined as seen in Table CXLVII.
(ii) Salicin of $3.3 \%$ solution was decomposed for 12 hours at $28^{\circ} \mathrm{C}$. To the data (E) I seems to be applicable as seen in Table CXLVIII.

## Amygdalase

Data obtained by Auld. ${ }^{(6)}$ Similarly to T. N. N. I and II for data obtained taking time as a variable, neither (E) I nor II is well applicable, as seen in Table CXLIX.

## 3. Recapitulation of results of application of T.N.N. (E) equations

As examined above T.N.N. (E) equations are not well applicable to data obtained with amylase, which can well be explained. To data obtained by amygdalse the equations are also not well applicable. The applicable equations to data obtained with other various enzymes could be determined the results of which are summarized in Table CL.

## Decomposition taking the quantity of substrate as a variable

For data obtained in the decomposition of substrates with various enzymes taking the length of time or the quantity of enzyme as a variable, the author has determined the best applicable equation, according to the kind of the enzyme or the kind of enzyme and substrate, with few exceptions. For data obtained in decomposition taking the quantity of substrate as a variable, not many equations have been proposed. All of them are very incomplete, similarly to various equations for data obtained in the previous two cases. In the study of soy bean proteins and oil the author decomposed the proteins with pepsin, pancreatin and papain, and oil with castor bean lipase and papain, taking the quantity of substrate as a variable. He endeavoured to find applicable equations to data thus obtained. He modified the T.N.N. equations. In the decomposition in this study, contrary to the decomposition in the previous two cases, the quantity of substrate decomposed
decreases with the increase of the quantity of substrate. Let S denote the quantity of substrate and $x$ the quantity of substrate decomposed in percentage. In applying the T.N.N. equations, $a-x$ was used instead of $x, S$ instead of $t$ in T. N. N. I and II and the following equations were obtained:

$$
\begin{aligned}
\frac{1}{S^{k^{\prime}}} \log \frac{a}{x} & =K, & & \text { (from T. N. N. I) } \\
\frac{1}{S^{k^{\prime}}} \frac{a-x}{a \cdot x} & =K . & & \text { (from T. N. N. II) }
\end{aligned}
$$

For the the sake of convenience the author named these equations T. N. N. (S) I and T. N. N. (S) II or briefly (S) I and (S) II respectively.

## 1. Results of application of T.N.N. (S) equations to published data

There have not been many available data obtained with various enzymes for finding applicable equations. Therefore the author cannot examine T.N.N. (S) equations for many enzymes by utilizing published data. The applicable T. N.N. (S) I or II for his own data and the results of application of them to previously published data obtained by preceding investigators are given below. In the tables the value of $100-x$ is given as the experimental value.

## Lipase

## 1) Castor bean lipase

(i) Data obtained by Nakajima in the decomposition of soy bean oil. (S) I is satisfactory. ${ }^{(49)}$
(ii) Data obtained by Jalander ${ }^{(38)}$ in the decomposition of olive oil. To the data of one of his results (S) I and II have been applied. In this case the probable errors are so large as to be 2 in both calculated results. The value of the difference for the and term is especially large in both results. (S) I and II have also been applied to the data omitting that term. As seen in Table CLI (S) I is certainly better than II. At the same time the result of the second term seems to be not accurate.
2) Papain

Data obtained by Narajima in the decomposition of soy bean oil. (S) II is satisfactory. ${ }^{\text {(49) }}$

## Emulsin

Data obtained by TammanN ${ }^{(70)}$ in the decomposition of amygdalin seem to follow (S) I as given in Table CLII. But the data are not adequate to examine the applicability of equations, for the range of decomposition is very narrow.

## Invertase

(i) Data obtained by Brown ${ }^{(12)}$ (S) I is satisfactory for Brown's data as shown in Table CLIII.
(ii) Data obtained by Barth. As shown in Table CLIV, Barth's data seem to follow (S) I, the first term of which is omitted in applying the equation, as the value of this term is larger than that of the second and is plotted certainly out of a smooth curve.

## Amylase

For data obtained by amylase taking the quantity of enzyme as a variable the author cannot find an applicable equation, which can be explained theoretically. For data obtained by taking the quantity of substrate as a variable, the same premise and conclusion-that there cannot easily be found any applicable equation--is theoretically suggested, as explained previously for data obtained by taking the quantity of enzyme as a variable.

## Maltase

Data obtained by Herzog, Becker and Kasarnowski ${ }^{(25)}$ seem to follow (S) I as seen in Table CLV.

## Pepsin

Data obtained by Nakajima in the decomposition of normal and denatured glycinins. (S) II is satisfactory. ${ }^{(49)}$

## Pancreatin

Data obtained by Nakajima in the decomposition of normal and denatured glycinins. (S) II is satisfactory. ${ }^{(49)}$

## Papain

Data obtained by Nakajima in the decomposition of normal and denatured glycinins. (S) I is satisfactory. ${ }^{(49)}$

Data obtained by Nakajima in the decomposition of normal and denatured glycinins. (S) I is satisfactory. ${ }^{\text {(49) }}$

## Protease

Data obtained by $\mathrm{WeIss}^{(73)}$ with germinated barley. (S) I is satisfactory as seen in Tables CLVI and CLVII.

## Phosphatase

Data obtained by Nemec ${ }^{(52)}$ with glycerophosphatase. (S) II is better than I as seen in Table CLVIII.

## 2. Recapitulation of results of application of T.N.N. (S) equations

From the above examination of equations for each kind of enzyme and substrate, the applicable equations are given in Table CLIX.

## Proposal of the theory of the constancy of the truly applicable equation to data obtained with a given kind of enzyme and a given kind of substrate

As already described, there has been no equation proposed as generally applicable and several kinds of equations have been usually proposed by diffesent investigators for data obtained with a given kind of enzyme and a given kind of substrate. It has been proved that T. N. N. I is widely applicable to data obtained with various enzymes. But one may consider that because the equation has two constants the probable error for T. N. N. I or II is little. To a certain extent this may be true. Although equations that have two constants each are few in enzyme chemistry, even such equations are also always unsatisfactory. Though T. N. N. I or II is generally satisfactory the author does not consider that it is because of its two constants. For trials, he formulated an equation, $\frac{1}{t^{t^{\prime}}} \log \frac{a+x}{a-x}=K$ which was obtained by subtituting $t^{t}$ for $t$ in Aberson's equation. The result of application of the former to data obtained by Aberson with zymase was less satisfactory than T. N. N. I, as already shown in Table CXXIII. On the contrary, for data obtained with amylase taking the relative quantity of enzyme as a variable T. N. N. I and II are not satisfactory, as already shown in Tables CXXXVII-CXXXIX. Although the experimental curves are very smooth, probable errors are comparatively large. T. N. N. III
was ascertained to be also not satisfactory. The same facts have also been observed for data obtained by using amylase in decomposition taking the quantity of substrate as a variable. The cause of this has been theoretically explained on page 162. Each T. N. N. equation has two constants, yet only one T.N.N. equation is the best applicable, according to the kind of enzyme or the kind of enzyme and substrate. From these observations it is clear that the fact that each T. N. N. equation has two constants is not the cause of its high applicability. It is necessary to consider the items given under paragraph 3 on page $1_{1}$ for examining the applicability of equations. In the study of a viscosity test of two miscible chemicals T. N. N. equations were proved to have a close relation to the chemical structure of the component. ${ }^{(49)}$

For data obtained with a given kind of enzyme and substrate more than two equations have been often maintained to be equally well applicable according to the experimental condition. The author considers that there can be only one definite equation which is fundamentally well applicable for such data notwithstanding the experimental condition. As to data obtained with a given kind of enzyme and substrate one of the T.N.N. equations is always satisfactory, i.e. the best applicable equation is always only one definite kind according to the relative properties of the enzyme and the substrate which satisfies the author's consideration above described. For instance the difference of chemism between pepsin and protein from that between trypsin and protein is yet not quite certain. But for the former enzyme, T. N. N. II is satisfactory, while for the latter T. N. N. I. T. N. N. equations are considered to be the general formulae of the equations that were theoretically deduced, such as the monomolecular and bimolecular equations. Therefore one can infer clearly the difference of the two enzymes in the chemism between the enzyme and the protein. The truly applicable equation is considered to be an important key to clear the chemism between the enzyme and substrate.

From the above considerations the author makes the following proposition:
"The truly applicable equation to data obtained with a given kind of cnzyme and substrate is always constant."

## Conclusion

The author has studied somewhat in the kinetics of enzymes. Some of the principal points are given below.
I. The principal equations proposed by preceding investigators in the study of decomposition by enzymes taking the length of time as a variable have been introduced. The author has shown that all these equations are usually not satisfactory even for the data of each original paper.
2. In the examination of the applicability of equations it is absolutely necessary to take care of several items, most of which have never been taught in enzyme chemistry. Without taking such care the proof of applicability of equations is incomplete. The items proposed by the present author are as follows:
a) For the experimental data to which the applicability is to be examined, it is necessary to attend to the following:

1) The range of decomposition must be wide.
2) The number of experimental terms must not be few.
3) If the experimental data of a result obtained in the decomposition by enzymes are plotted, and if they are accurate, they are to be on a smooth curve. In the special case of one or a few points which are certainly known at a glance to be out of a smooth curve, that datum or those data must be omitted from calculation in applying equations.
4) The nature of the equation to be examined and the nature of the experimental curve must be the same.
b) In estimating the applicability of equations it is necessary to examine :
5) Not only the uniformity of the values of the constant of the equation but also the magnitude of the mean value of the differences between experimental and caluculated values.
6) Whether or not the value of the constant of an equation or the value between experimental and calculated values varies in a certain definite tendency.
3. The equation, $\frac{1}{t^{t}} \log \frac{a}{a-x}=K$, which was before formulated by the present author, and Nakamura's equation, $\frac{1}{t^{t^{\prime}}} \frac{x}{a(a-x)}=K$ were named for the sake of convenience T. N. N. I and II respectively. These have already been stated to be the general formulae of equations of the first and second order respectively. T. N. N. equations for the higher orders are considerd in the present paper.
4. The meaning and importance of the applicability of equations
has been shown, and examples showing the imperfection or mistakes of some theories which were deduced from mistaken recognition of applicability of equations in enzyme chemistry have been given.
5. It has been shown that data obtained in the decomposition by enzymes followed T. N. N. I or II with few exceptions. The applicable equations for various enzymes have been determined.
6. The Schütz law $\frac{x}{\sqrt{E}}=K$, which was formerly accepted by the precent author for only dilute pepsin, has been refuted.
7. All the equations that have been proposed to be well applicable to data obtained in decomosition taking the relative quantity of enzyme as a variable have been considered to be not applicable.
8. Let $E$ be the relative quantity of enzyme and $x$ the quantity of substrate decomposed and $a$ the quantity of substrate taken. The modified formulae of T. N. N. equations which were obtained before by substituting $E^{t^{\prime}}$ for $t^{t^{\prime}}$ in T. N. N. equations were named T. N. N. (E) equations. Their applicability had already been examined for data obtained in the decomposition of soy bean protein and oil.
9. To the data of the principal published reports, T. N. N. (E) equations have been applied and the applicable equations have been determined for various enzymes with few exceptions. Similarly to the data obtained in the decomposition taking time as a varible, some one of the T.N.N. (E) equations is always applicable, according to the kind of substrate and enzyme.
ro. To data obtained in decomposition taking the quantity of substrate as a variable, the modified formulae of T.N.N. I and II, $\frac{1}{S^{k^{\prime}}} \log \frac{a}{x}=K$ and $\frac{1}{S^{k^{\prime}}} \frac{a-x}{a \cdot x}=K$, where $S$ was the quantity of substrate taken have been gotten. They were named T.N.N. (S) equations. To the author's data and the principal published data they have been applied and the best applicable equation was determined for each kind of enzyme and substrate.
II. Only for data obtained with amylase the applicable T. N. N. (E) or T. N. N. (S) equation could not be determined. The reason was theoretically discussed.
10. The theory of the constancy of a truly applicable equation has been proposed.

The author wishes to expresss his thankful appreciation to Prof. T. Tadokoro under whose constantly kind istruction the author completed this work.

The author wishes to thank also Mr. K. Sugivama, President of the Honen Oil Co., Ltd., for his sympathetic interest and encouragement, while the author was carrying on this investigation under the auspices of the company at the laboratory of Prof. Tadokoro in the Faculty of Agriculture, Hokkaido Imperial University.
