HOKKAIDO UNIVERSITY
In the second study gravid cows were found to show prominent sclerotic changes in the tunica intima of their arteriae uterinae mediae, i.e. prominent hyperplastic swelling of the tunica intima, hyperplastic smooth muscle fibers and interstitial ground substance. In the region of hyperplastic swelling of the tunica intima, one or more concentric layers of elastic membrane are clearly seen. This appearance is considered to represent gravidity sclerosis in the cow.

In many cases (35%) the number of layers of elastic membrane is exactly the same as the parturition frequency. The appearance of sclerotic gestation layers ("sclerotic gestation rings", which TAKAHATA and others advocated) becomes more noticeable as parturition frequency increases.

**STUDIES ON RESPONSES TO MORPHINE HYDROCHLORIDE IN DOGS AND SOME CLINICAL EVALUATIONS**

The experiment was conducted to establish criteria for the use of morphine in veterinary clinics. A one percent solution of morphine hydrochloride was administered to dogs, either intravenously (A₁) or subcutaneously (A₂) in doses of 1 mg (D₁), 10 mg (D₂) and 30 mg (D₃) per kg of body weight, and comparative biochemical studies and clinical examinations were carried out immediately, 24 hours following administration.

The results may be summarized as follows:

The difference between A₁ and A₂ was significant in the changes of eosinophil count, blood sugar, blood CO₂, blood Pco₂, blood HCO₃⁻, blood H₂CO₃ and blood B₈, and was insignificant in the changes of red cell count, white cell count, blood O₂, blood pH and Ht. Comparison between A₁ and A₂ generally indicated that A₁ produced not only a more rapid effect, but smoother recovery.

Comparison between D₁, D₂ and D₃ indicated that an increased dosage produced increased effect. Only slight changes were produced by D₁, but considerable changes were observed by D₂ and D₃. Changes of serum proteins and liver functions were slight, irrespective of the administered methods or doses.

In clinical symptoms, the considerable difference between A₁ and A₂ was the

appearance of remarkable agitation, fall of blood pressure and respiratory depression in A₁ and the appearance of emesis in A₂. Observed clinical symptoms indicated that D₁ produced either no effect or only sedative effect while D₂ and D₃ produced surgical anesthesia in most cases, either A₁ or A₂.

It is concluded that morphine is unsuitable as general anesthetic for dogs because of its side effects, but it is felt that small doses of morphine (about 1 mg/kg) are very useful as pre-anesthetic, basal anesthetic or sedative, especially when administered intravenously.
