Two new metastrongylid nematodes from Thailand were described. Angiostrongylus siamensis sp. n. was found in the mesenteric arteries of Rattus sabanus. This species is related to A. costaricensis, but is differentiated by a more reduced bursa in the male and a longer tapered tail in the female. Thaistrongylus harinasutai gen. et sp. n. was found in the lungs of Rattus herdmorei. In the male the bursa very reduced; the dorsal rays subventral showing a pair of papillae; other rays short and stout; the spicules short and arcuate; and a gubernaculum present. The female ovoviviparous, and the tail short and rounded.

INTRODUCTION

In Thailand micromammal fauna is plentiful because of the zoogeographical situation. Among various mammals those of the family Muridae are believed to have originated in the oriental region, and the genus Rattus in Thailand comprises more than 20 species. The authors studied the parasites mainly of the genus Rattus. Our hypothesis was that many angiostrongylid and nippostrongylid nematode species can be obtained from various rats. In this paper two new nematodes belonging to Metastrongyloidea are described.

MATERIALS AND METHODS

During the period from July 18 to August 7, 1978, various micromammals were collected at Bangkok, Sai Yok, Nakorn Nayok, Mae Hongson and Mae Sariang. Among

*2 Department of Helminthology, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand.
the 144 specimens collected 72 belonged to the genus *Rattus*, viz., 26 to *R. exulans*; 10 to *R. surifer*; 3 to *R. bükít*; 4 to *R. sabauns*; 12 to *R. norvegicus*; 15 to *R. rattus* and 2 to *R. berdmorei*, and the remaining 72 comprised the genera *Mus*, *Hylopetes*, *Crocidura*, *Tupaia*, *Hipposideros*, *Myotis*, etc. Among these, metastroglycid nematodes were found in both *R. sabauns* and *R. berdmorei*.

The nematodes were collected using the dissection microscope and then preserved in 5% formalin solution. The specimens were treated with lacto-phenol solution for microscopy. All of the specimens are deposited in the helminthological collection of the Department of Parasitology, Faculty of Veterinary Medicine, Hokkaido University, Japan.

**Results**

1) *Angiostrongylus siamensis* sp. n.

One of 4 specimens of the noisy rat, *Rattus sabauns*, captured at Nakorn Nayok, 100 km northeast to Bangkok, was positive for granulomatous thickening of the upper colon. A small number of complete and fragmented nematodes from the regional mesenteric arteries were collected. A histological examination revealed granulomatous reactions against the larval nematodes. One male and 5 females were used for the description.

**Host:** *Rattus sabauns* (Thomas)

**Habitat:** Mesenteric arteries

**Locality:** Nakorn Nayok, Thailand

**Date collected:** July 23, 1978

**Description:** Filiform nematode. Cuticle smooth. Cephalic end slightly inflated. Wall of mouth cavity not chitinized.

One male, 10 mm in length. Caudal end bent ventrally. Esophagus 0.23 mm in length. Excretory pore 0.32 mm from cephalic end. Bursa pouch and reduced. Bursal rays short. Ventral rays rise separately from laterals, fused except for distal one fourth; ventro-ventral shorter than latero-ventral. Laterals with common trunk, shorter than ventrals; medio-lateral longest. Externo-dorsal shorter than laterals. Dorsal mound-like with a pair of short digitiform projections. Spicules filiform and short, 0.339 mm in length; each with two alae, stem with rounded distal end. Gubernaculum weakly chitinized and undulated, 0.040 mm in length.

Five females, body length 11–13 mm. Caudal end coiled ventrally. Esophagus 0.23–0.27 mm in length. Excretory pore 0.32–0.36 mm from cephalic end. Vulva 0.30–0.38 mm from caudal end. Tail 0.07–0.10 mm in length, tapering distally, end bluntly pointed without projection.

**Discussion:** This species is the first recorded of the mesenteric angiostrongyly in Eurasia. Among various *Angiostrongylus*-species, the only comparable species is
Figure 1 Angiostrongylus siamensis sp. n.

1 Anterior end of female, 2 Posterior end of male, 3 Bursa, ventral view, 4 Gubernaculum, 5 Bursa, lateroventral view, 6 Distal end of spicules, 7-11 Posterior end of female.
A. costaricensis Morera et Cespedes, 1971, to which A. siamensis shows similarities in morphology and habitat. However, in the strain of A. costaricensis of the authors' laboratory, the spicules are shorter than those of A. siamensis. The end of the spicule stem has a minute projection, the ventral rays are much longer than the laterals, the length of the externo-dorsal ray is the same as the postero-lateral, and the dorsal ray is composed of a thick trunk with two short branches. In the female the tail of A. costaricensis is shorter, and the caudal end is rounded and shows a minute projection.

The authors have succeeded in the laboratory rearing of A. siamensis using Biomphalaria and laboratory animals; the detailed results will be published separately.

2) Thaistrongylus harinasutai gen. et sp. n.

One of 2 specimens of the lesser white-toothed rat, Rattus berdmorei, captured at Mae Sariang, 150 km southwest to Chiang Mai, harbored lungworms in the lungs and showed circumscribed convex foci. A conglomeration of worms was observed in the focus. No complete specimens of the worms were collected, and the description was based on fragmented worms.

Host: Rattus berdmorei Blyth
Habitat: Lungs
Locality: Mae Sariang, Thailand
Date collected: August 7, 1978
Description: Filiform nematode. Caudal end tapered. Cuticle smooth. Mouth with four lips.

One male, maximal width 0.18 mm. Esophagus 0.167 mm in length. Nerve ring and excretory pore 0.083 mm from cephalic end. Spicules equal, short and arcuate, 0.106 mm in length. Gubernaculum 0.030 mm in length, distal end thickened. Bursa bilobed, strongly reduced, about 0.065 mm in diameter. Bursal rays, with exception of dorsal ray, short and stout; ventrals and laterals with thick common trunk, each ray differentiable by shallow incisions. Dorsal ray exists subventrally as a pair of minute papillae.

One female, ovoviviparous, maximal width 0.24 mm. Esophagus 0.216 mm in length. Nerve ring and excretory pore 0.125 mm from cephalic end. Vulva and anus 0.080 and 0.020 mm from caudal end. Tail rounded.

Type species: Thaistrongylus harinasutai sp. n.

Discussion: Thaistrongylus is characterized by strongly reduced bursa, papilla-like dorsal ray and short arcuate spicules. Morphology of the bursa is related to that of Marsupiostrongylus Mackerras et Sandars, 1953, and Andersonstrongylus Webster,
Parasite fauna of Thailand 1

FIGURE 2  Thaistrongylus harinasutai gen. et. sp. n.

1 Anterior end of male, 2 Posterior end of male, lateral view, 3 Posterior end of male, dorsal view, 4 Bursa, ventral view, 5 Posterior end of female

1978. In Marsupostrongylus, bursal rays are well-developed, although the dorsal ray is papilla-like. On the other hand, in Andersonstrongylus, the bursa is strongly reduced, and the externo-dorsal and dorsal rays manifest a minute papilliform structure. Consequently, in the grade of reduction of bursa, Thaistrongylus is in between these two genera, although the host ranges are quite different.

ACKNOWLEDGEMENTS

The authors wish to express their thanks to Prof. Chamlong Harinasuta, dean of the Faculty of Tropical Medicine, Mahidol University, for his support. The materials
were made available by Prof. Hisashi Abe, Department of Applied Zoology, Faculty of Agriculture, Hokkaido University, and Mr. Somchai Imlarp, Department of Tropical Hygiene, Faculty of Tropical Medicine, Mahidol University.
