# A STUDY ON THE CORRECTION OF MAGNETIC COMPASS 

Masaski HYUGA<br>Faculty of Fisheries, (Hakodate) Hokkaido University

## (1) Introduction

The writer proposed of a method to correct the magnetic compass by the observations of deviations of the compass and directive force of its needles on two or a single heading.

The methods generally followed necessitate keeping ship's head on four cardinal and intercardinal points by compass or magnetic bearing. However, this is a method to correct the compass by assertaining the coefficients by keeping ship's head on any given two or a single heading.

## (2) Method

§1. Formulae.
The formulae for this purpose can be as follows:
The following Poisson's equation repre-

In figure (above), let $X, Y$ ard $Z$ represent the respective axes of slip's fore and aft direction, athwartship direction and vertical direction. magnetic field,
Z : Vertical component of Earth's magnetic field,
I : Dip,
$\theta$ : Compass heading,
$\delta_{0}$ : Deviation for $\theta$,
and $\mathrm{H}_{6}$ : Horizontal component of ship's magnetic field.
Then,

$$
\left\{\begin{array} { l } 
{ \mathrm { X } = \mathbf { H } \operatorname { c o s } ( \theta + \delta _ { 0 } ) } \\
{ \mathbf { Y } = - \mathbf { H } \operatorname { s i n } ( \theta + \delta _ { 0 } ) }
\end{array} \quad \left\{\begin{array}{l}
\mathrm{X}^{\prime}=\mathbf{H}_{y} \cos \theta \\
\mathrm{Y}^{\prime}=-\mathbf{H}_{y} \sin \theta
\end{array}\right.\right.
$$

and $Z=H \tan I$
Therofora Poisson's equation (1) becomes

$$
\begin{align*}
\mathrm{H}_{\theta} \cos \theta & =(1+\mathrm{e}) \mathbf{H} \cos \left(\theta+\delta_{\sigma}\right)-\mathrm{bH} \sin \left(\theta+\delta_{\theta}\right)+\mathrm{eH} \tan \mathrm{I}+\mathrm{P} \\
-\mathrm{H}_{\theta} \sin \theta & =-(1+\mathrm{e}) \mathrm{H} \sin \left(\theta+\delta_{\sigma}\right)+\mathrm{dH} \cos \left(\theta+\delta_{\theta}\right)+\mathrm{fH} \tan \mathrm{I}+\mathrm{Q} \tag{2}
\end{align*}
$$

Let

$$
\begin{array}{ll}
\mathbf{A}_{0}=\frac{1}{\lambda}\left(\frac{\mathrm{~d}-\mathrm{b}}{2 \cdot}\right), & \mathrm{D}_{0}=\frac{1}{\lambda}\left(\frac{\mathrm{a}-\mathrm{e}}{2}\right) \\
\mathrm{B}_{\theta}=\frac{1}{\lambda}\left(\mathrm{c} \tan \mathrm{I}+\frac{\mathrm{P}}{\mathrm{H}}\right), & \mathrm{E}_{0}=\frac{1}{\lambda}\left(\frac{\mathrm{a}+\mathrm{b}}{2}\right) \\
\mathrm{C}_{\theta}=\frac{1}{\lambda}\left(\mathrm{ftan} \mathrm{I}+\frac{\mathrm{Q}}{\mathrm{H}}\right), & \lambda=1+\frac{\mathbf{a}+\mathrm{e}}{2}
\end{array}
$$

Here $A_{0}, B_{0}, C_{0}, D_{0}$ and $E_{0}$ are called the Exact Coefficients of Deviations, and $\lambda$ horizontal shielding factor. Generally $A_{0}$ and $E_{0}$ are very small. Therafore, if $A_{0}$ and $E_{0}$ are assumed respeotively zero, then $b$ and $d$ are regarded zero.

Therefors, (2) becomes

$$
\begin{align*}
\frac{\mathrm{H}_{\theta}}{\mathrm{H}} \cos \theta & =(1+\mathrm{e}) \cos \left(\theta+\delta_{\theta}\right)+\lambda \mathrm{B}_{\mathbf{0}}  \tag{3}\\
-\frac{\mathrm{H}_{\theta}}{\mathrm{H}} \sin \theta & =-(1+\mathrm{e}) \sin \left(\theta+\delta_{\sigma}\right)+\lambda \mathrm{C}_{\theta}
\end{align*}
$$

If a and e are expressed in $D_{0}$, (3) becomes

$$
\begin{align*}
& \mathrm{B}_{0}=\frac{\mathrm{H}_{\theta}}{\lambda \mathrm{H}} \cos \theta-\left(1+\mathrm{D}_{0}\right) \cos \left(\theta+\delta_{b}\right)  \tag{4}\\
& \mathrm{C}_{0}=-\frac{\mathrm{H}_{\theta}}{\lambda \mathrm{H}} \sin \theta+\left(1-\mathrm{D}_{0}\right) \sin \left(\theta+\delta_{\theta}\right)
\end{align*}
$$

§ 2. Compensation on two headings.
This can be done with a considerable accurasy for directive force on two headings, the only assumption being that the coefficients $A_{0}$ and $E_{0}$ are zero, which is generully true.

Two headings are available :
a) When a ship is moored alongside of a wharf or pier and afterward winded and moored on the opposite heading or another differant heading.
b) When a ship is moored alongside of a wharf or pier, and before and afterward, when she is off them, - for instance entsring or leaving harbor.
c) When a ship attained two of her courses at sea. (desirable in the harbor.)

The ship must not, in eash case, be newr another iron or steal ship or in the immediate vicinity of iron or stosl stractures on shors.

Now let $\theta_{1}$ and $\theta_{2}$ denote two respective ship's compass headings, $\delta_{\sigma_{1}}$ and $\delta_{02}$ the corresponding deviztions for two compass headings $\theta_{1}$ and $\theta_{2}, \mathrm{n}$ a raading shown on the scale when the North point of the compass carl was deflected by $45^{\circ}$ or $96^{\circ}$ by deflector, on shore in a place fres from local mageetic influences, and not greatly distant from the ship, $n \theta_{1}$ and $n \theta_{0}$ the raspetive randings shown on the siale for two compass headings $\theta_{1}$ and $\theta_{2}$ when the same point was deflected by the same angle by defleator on board the ship in the exact position of the compass needle, and $\mathrm{H}_{61}$ and $\mathrm{H}_{62}$, the respective ship's horizontwl magnetic fields for two compess headings.

Then the equation (3) for each compass heading $\theta_{1}$ and $\theta_{2}$ becomes respectively,

$$
\begin{align*}
& \frac{\mathrm{H}_{b_{1}}}{\mathrm{H}} \cos \theta_{1}=(1+\mathrm{a}) \cos \left(\theta_{1}+\delta_{\sigma_{1}}\right)+\lambda \mathrm{B}_{0} \\
& \left.\frac{\mathrm{H}_{\delta \mathrm{g}}}{\mathrm{H}} \cos \theta_{2}=(1+\mathrm{a}) \cos \left(\theta_{2}+\delta_{\delta_{2}}\right)+\lambda \mathrm{B}_{0}\right)  \tag{;}\\
& \therefore \quad 1+\mathrm{a}=\frac{\frac{\mathrm{H}_{\theta} 1}{\mathrm{H}} \cos \theta_{1}-\frac{\mathrm{H}_{\theta_{2}}}{\mathrm{H}} \cos \theta_{2}}{\cos \left(\theta_{1}+\delta_{\sigma_{1}}\right)-\cos \left(\theta_{2}+\delta_{\sigma_{2}}\right)} \ldots \cdots \tag{6}
\end{align*}
$$

In like manner,

$$
\left.\begin{array}{l}
-\frac{\mathrm{H}_{\theta_{1}}}{\mathrm{H}} \sin \theta_{1}=-(1+\mathrm{e}) \sin \left(\theta_{1}+\delta_{\sigma_{1}}\right)+\left.\lambda \mathrm{C}_{0}\right|_{1} \\
-\frac{\mathrm{H}_{\theta 2}}{\mathrm{H}} \sin \theta_{2}=-(1+\mathrm{e}) \sin \left(\theta_{2}+\delta_{\theta_{2}}\right)+\lambda \mathrm{C}_{0} \tag{8}
\end{array}\right) .
$$

$\lambda$ and $D_{0}$ are given by

$$
\begin{gathered}
\lambda=1+\frac{a+e}{2}=\frac{1}{2}\{(1+a)+(1+e)\} \\
D_{0}=\frac{1}{\lambda}\left(\frac{a-e}{2}\right)=-\frac{1}{\lambda}\left\{\frac{(1+a)-(1+e)}{2}\right\}
\end{gathered}
$$

and from (5) and (7),

$$
\begin{align*}
& \mathrm{B}_{0}=\frac{1}{2 \lambda}\left(\left(\frac{\mathrm{H}_{\sigma_{1}}}{\mathrm{H}} \cos \theta_{1}+\frac{\mathrm{H}_{\sigma_{2}}}{\mathrm{H}} \cos \theta_{s}\right)-(1+\mathrm{a})\left\{\cos \left(\theta_{1}+\delta_{\sigma_{1}}\right)\right.\right. \\
& \left.+\operatorname{coss}\left(\theta_{2}+\delta_{o_{2}}\right)\right\} ; \ldots .  \tag{9}\\
& \mathrm{C}_{0}=\frac{-1}{2 \lambda}\left(\left(\frac{\mathrm{H}_{61}}{\mathrm{H}} \sin \theta_{1}+\frac{\mathrm{H}_{\theta 2}}{\mathrm{H}} \sin \theta_{2}\right)-(1+\mathrm{e})\left\{\sin \left(\theta_{1}+\delta_{\theta_{1}}\right)\right.\right. \\
& \left.+\sin \left(\theta_{2}+\delta_{\theta_{2}}\right)\right\}, \tag{10}
\end{align*}
$$

Then $\operatorname{since} \frac{H_{\theta}}{H}=\frac{n_{\theta}}{n}$, (9) and (10) can be written

$$
\begin{aligned}
& B_{0}=\frac{1}{2 \lambda}\left(\left(\frac{n_{\theta 1}}{n} \cos \theta_{1}+\frac{n_{\theta q}}{n} \cos \theta_{2}\right)-(1+a)\left\{\cos \left(\theta_{1}+\delta_{\theta_{1}}\right)\right.\right.
\end{aligned}
$$

$$
\begin{align*}
& \mathrm{C}_{0}=\frac{-1}{2 \lambda}\left\{\left(\frac{\mathrm{n}_{\theta_{1}}}{\mathrm{n}} \sin \theta_{1}+\frac{\mathrm{n}_{\theta_{2}}}{\mathrm{n}} \sin \theta_{2}\right)-(1+\theta)\left\{\sin \left(\theta_{1}+\delta_{\theta_{1}}\right)\right.\right.  \tag{11}\\
& \left.\left.+\sin \left(\theta_{2}+\delta_{\theta_{2}}\right)\right\}\right\} \tag{12}
\end{align*}
$$

Substituting the values of $\lambda,(1+a)$ and $(1+e)$ into the equations (11) and (12), $\mathrm{B}_{0}$ and $\mathrm{C}_{0}$ can be obtained.

Now if the approximate coefficients are expressed by $A, B, C, D, E ;$ and the deviation $\delta_{\theta}$ for compass heading $\theta$, in degrees,

$$
\begin{equation*}
\delta_{\theta}=\mathrm{A}+\mathrm{B} \sin \theta+\mathrm{C} \cos \theta+\mathrm{D} \sin 2 \theta+\mathrm{E} \cos 2 \theta \tag{13}
\end{equation*}
$$

Then the relation between the exact coefficients and approximate coefficients is as follows:

$$
\begin{array}{lll}
\mathrm{A}_{0}=\sin \mathrm{A}, & \mathrm{~B}_{0} \fallingdotseq \sin \mathrm{~B}, & \mathrm{C}_{0} \fallingdotseq \sin \mathrm{C} \\
\mathrm{D}_{0} \fallingdotseq \sin \mathrm{D}, & \mathrm{E}_{0} \fallingdotseq \sin \mathrm{E}, & \mathrm{E}_{0}=\sin \mathrm{E}-\left.\sin \mathrm{A} \sin \mathrm{D}\right|^{-} \tag{14}
\end{array}
$$

Now since $A_{0}$ and $\mathbf{E}_{0}$ are respectively zero, $A$ and $E$ accordingly become zero.
Therefore (13) can be written

$$
\begin{equation*}
\delta_{\theta}=\mathrm{B} \sin \theta+\mathrm{C} \cos \theta+\mathrm{D} \operatorname{sind} 2 \theta- \tag{15}
\end{equation*}
$$

From (14) it follows that

$$
\mathrm{B}=\mathrm{B}_{0} \times 57^{\circ} .3, \quad \mathrm{C} \fallingdotseq \mathrm{C}_{0} \times 57^{\circ} .3, \quad \mathrm{D} \fallingdotseq \mathrm{D}_{0} \times 57^{\circ} .3
$$

So that, $\mathrm{B} \sin \theta_{2} \fallingdotseq \mathrm{~B}_{0} \sin \theta_{2} \times 57^{\circ} .3$ is the amount to be corrected by fore and aft magnets for ship's compass heading $\theta_{2}$.
$\mathrm{C} \cos \theta_{2} \fallingdotseq \mathrm{C}_{0} \cos \theta_{2} \times 57^{\circ} .3$ is the smount to be corrected by athwartship magnets for ship's compass heading $\theta_{2}$.

D $\sin 2 \theta_{2} \fallingdotseq \mathrm{D}_{0} \sin 2 \theta_{9} \times 57^{\circ} .3$ is the amount to be corrected by iron spheres for ship's compass beading $\theta_{2}$.
Example:
When the following data in a certain ship are observed, the compensation on 2nd heading is required.

$$
\begin{array}{rlr}
\theta_{1} & =45^{\circ} 45^{\prime} & \delta_{\theta 1}=12^{\circ} 15^{\prime} \mathbf{E} \\
\theta_{2} & =245^{\circ} & \delta_{\theta 2}=7^{\circ} 00^{\prime} \mathrm{W} \\
\mathbf{n}_{\theta_{1}} & =22.7 & \mathbf{n}_{\theta_{2}}=9.1 \\
\mathrm{n} & =17.8 &
\end{array}
$$

Using the equations (6), (8), (11) and (12), the following values are obtained:

$$
\begin{array}{llll}
1+2=1.043 & \lambda=0.927 & \mathrm{D}_{0}=+0.125 & \mathrm{C}_{0}=-0.2445 \\
1+\mathrm{e}=0.811 & & \mathrm{~B}_{0}=+0.365 &
\end{array}
$$

Then the amonnts to be corractod on ship's compass heading $245^{\circ}$ are,
$\mathrm{B} \sin \theta_{2} \fallingdotseq \mathrm{~B}_{0} \sin \theta_{2} \times 57^{\circ} 3 \fallingdotseq-18.9$
$\mathrm{C} \cos \theta_{2} \fallingdotseq \mathrm{C}_{0} \cos \theta_{2} \times 57.3 \fallingdotseq+5.9$
$\mathrm{D} \sin 2 \theta_{2} \fallingdotseq \mathrm{D}_{2} \sin 2 \theta_{2} \times 57 .^{\circ} 3 \fallingdotseq+5.5$
Then of these velues, $-18^{\circ} 9$ due to $B_{0}$ is to be compensated by fore and aft magnets, +5.9 due to $\mathrm{C}_{0}$ by athwartship magnets and $+5 .{ }^{\circ}$ a due to $\mathrm{D}_{0}$ by iron spheres. § 3. Compens.tion on one heading

Should it not be possible to take observations for dirastive forse on two headings, the comp:ss can be corrected with tolerable accuricy from observations on one heading only. Center the compass accurately, place the spheras by estimate, and then compens:te the heeling error rog.wrdess of the fact that the ship may not be heading near East or West.

Next, record the compass heading of the ship by compass to be corrected. And observe and racord the magnetio heading obtainable by means of a chart, or an azimoth of the sun, or of a distant object of known magnetic besring, or by a single set of raciprocal bearings.
Let $\theta$ denote ship's compass heading,
$\delta_{\theta}$ : deviation for $\theta$
n : a raading shown on the sale when the North point of the compass card was deflected by $45^{\circ}$ or $96^{\circ}$ by deflestor, on shore in a place frie from local magnetic influences, and not graitly distant from the ship
$n_{\theta}$ : a reading shown on the saale for ship's compass heading $\theta$ when the same point was deflected by the same angle by deflector on board the ship in the exact position of the compess needle
And then using the equation (4), $B_{0}$ and $C_{0}$ aro obtained as follows:

$$
\left.\begin{array}{l}
\mathrm{B}_{0}=\frac{1}{\lambda} \frac{\mathrm{n}_{\theta}}{\mathrm{n}} \cos \theta-\left(1+\mathrm{D}_{0}\right) \cos \left(\theta+\delta_{\theta}\right) \\
\mathrm{C}_{0}=\frac{-1}{2} \frac{\mathrm{n}_{\theta}}{\mathrm{n}} \sin \theta+\left(1-\mathrm{D}_{0}\right) \sin \left(\theta+\delta_{\theta}\right) \tag{16}
\end{array}\right\}
$$

In this event the quadrantal spheres must be placed by estimate and values of $\lambda$ and $D_{0}$ essumed; the value of $\lambda$, being generally 0.70 to 0.95 average, may be assumed as approximately 0.9 when $\lambda$ cannot be observed. In the same manner as in the compensation on two headings, $\mathrm{B}_{0}, \mathrm{C}_{0}$ and $\mathrm{D}_{0}$ can be exprassed by $\mathrm{B}, \mathrm{C}$ and D , and the deviation may be compens ated on any compass heading es desired. Viz.

Let $\mathrm{D} \sin 2 \theta=\mathrm{D}_{0} \sin 2 \theta \times 57.0^{\circ} 3$ be the amount to have been compensated by iron spheres assuming the values of $\mathrm{D}_{\boldsymbol{0}}$ ，and then $\mathrm{B} \sin \theta \leftrightharpoons \mathrm{B}_{\mathbf{0}} \sin \theta \times 57 .^{\circ} 3$ is the amount to be compensated by fore and aft magnets，and $\mathrm{C} \cos \theta \fallingdotseq \mathrm{C}_{0} \cos \theta \times 57 .^{\circ} 3$ the amount to be compensated by athwartship magnets．
Example：
From data for standard compass of a similar ship，assumed：And estimated that the deviation due to $\mathrm{D}_{0}$ has been compensated by iron spheres．It is then found that：

$$
\begin{array}{lc}
\theta=21^{\circ} & \delta_{g}=5^{\circ} 10^{\prime} \mathrm{W} \\
\mathrm{n}=25.3 & \mathrm{n}_{g}=14.8
\end{array}
$$

Compensate on ship＇s compass heading 21．${ }^{\circ}$
Using（16），the following values are obtained：
$\mathrm{B}_{0}=-0.35 . \quad \mathrm{C}_{0}=+0.04$
Therefore the amount to be compensated on compass heading are，
$B \sin \theta \fallingdotseq \mathrm{~B}_{0} \sin \theta \times 57 .{ }^{\circ} 3 \fallingdotseq-7 . .^{\circ} 2$
$\mathrm{C} \cos \theta \fallingdotseq \mathrm{C}_{0} \cos \theta \times 57.3 \fallingdotseq+2.1$
Of these values，$-7 .{ }^{\circ} 2$ is to be compensated by fore and aft magnets，and $+2 .{ }^{\circ} 1$ by athwarlship magnets．

In such ceses as described above in the compensations on two or a single head－ ing，the computed values of these portions $\mathrm{B} \sin \theta+\mathrm{C} \cos \theta$ may differ appreciably from the actual values of $\delta_{\theta}$ ；this is due to the reason that the relation between the Approximate and Exact Coefficients of Deviations in（13）has been required approximately．
$\S$ 4．Analysis of Coofficient $\mathrm{B}_{0}$
As the analysis of coefficient $B_{0}$ was described in the previous report by the writer，this subjest is herein omitted．

## （3）Conclusion

The writer considers that this may be good enough to adopt as a method to correct the compass on two or a single heading in taking advantage of the time when a ship is being moored or lying in the harbor．

As the coeffieients $A_{0}$ and $E_{0}$ are supposed zero and the formulae used in com－ putations are obtained approximately，this cannot be oalled an absolutely perfect method．However，the writer believes that this is well adopted for the practical use of magnetic compass corraction，and navigators are enrnestly requested to pay attention to this work and to try this method at sea．
