THEORY OF HYDROGENATION OF ETHYLENE ON METALLIC CATALYSTS

III. Theoretical Relations between Equilibrium Fraction, Deuterium Atomic Fraction and Partial Pressure of Hydrogen in Course of Catalyzed Hydrogenation of Ethylene in the Presence of Nickel Catalyst

By

Jura Horiuti* and Isao MatsuZaki* (Received December 10, 1959)

Introduction

It has been shown in Part I** of this series that the rate of the catalyzed hydrogenation*** in the presence of metallic catalysts and those of associated reactions are given as functions of characteristic rate functions $\xi(s)$'s respectively relevant to constituent steps $s$'s of the overall reaction (1). $\xi(s)$ is the forward rate of step $s$ at the steady state of the overall reaction (1) multiplied by a factor $a_{i}^{(s)}/a_{j}^{(s)}$ of increase of the activity of the initial complex $I(s)$ from that $a_{i}^{(s)}$ at the latter steady state to that $a_{j}^{(s)}$ at equilibria of all constituent steps but $s$.

Assuming a bare and homogeneous catalyst's surface, $\xi(s)$'s were statistically-mechanically formulated in Part III particularly for the associative mechanism, i.e.

$$C_{2}H_{4} + H_{2} = C_{2}H_{6}$$  (1)

* Research Institute for Catalysis, Hokkaido University.

** Protium and deuterium atoms are denoted by $P$ and $D$ respectively, they together represented by $H$ and called hydrogen atoms as in Parts I and II.

*** They are exchange reaction of ethylene, that of hydrogen, equilibration of hydrogen ($P_{2} + D_{2} = 2PD$), parahydrogen conversion and evolution of different deuterocompounds of ethylene, hydrogen and ethane in course of the catalyzed hydrogenation. The rate of exchange $E^e$ of ethylene ($E$) and that $E^n$ of hydrogen ($H$) respectively defined as

$$E^e = n^e\dot{X}/(Y - X)$$  \hspace{1cm} $$E^n = n^n\dot{Y}/(X - Y)$$

are not necessarily identical with each other as shown in Part I (Ref. 1), where $n^e$ or $n^n$ is number of hydrogen atoms implied in $E$ or $H$, $X$ or $Y$ the deuterium atomic fraction of $E$ or $H$ and $\dot{X}$ or $\dot{Y}$ its time derivative, unless there exists such a relation $n^e\dot{X} + n^n\dot{Y} = 0$ as in simple cases of exchange reaction, when $n^e$, $n^n$ and the total amounts of isotopes involved remain respectively unchanged.

---

187
as functions of partial pressures $P^E$ and $P^H$ of $E$ and $H$, each including the appropriate activation energy as a unique adjustable parameter; the latter being fitted to experiment or estimated theoretically, a number of experimental results were accounted for and several experimentally verifiable conclusions derived on the basis of the associative mechanism (2)<sup>10</sup>. Among others the following result of Twigg and Rideal<sup>9</sup> was semiquantitatively explained on their basis.

Twigg and Rideal<sup>9</sup> have observed that in the catalyzed interaction of 10 mmHg ethylene with equimolecular deuterium at different temperatures ranging from 84 to 207°C in the presence of Ni-catalyst, the non-equilibrium fraction<sup>*)</sup> $1-u$ varied linearly with the deuterium atomic fraction $Y$ of hydrogen, and that the linear relation stayed constant from 84°C to 156°C, extrapolating $1-u=0.8$ at $Y=1$ but deviated from the constant one with rise of temperature above 156°C, $1-u$ extrapolated at $Y=1$ decreasing down to 0.4 at 207°C.

Twigg and Rideal<sup>9</sup> based their mechanisms proposed against the associative mechanism on the above experimental fact of the constant linear relation being kept up between 84°C and 156°C, disregarding the deviation from it at higher temperatures. It was shown in terms of the above simplified functions of $\xi(s)$'s in Part I<sup>9</sup>, that the limiting value of $1-u$ for $Y\rightarrow 1$ stays constant at lower temperature but decreases at higher temperature in accordance with their experimental result<sup>9</sup>.

The simplifying assumption of bare catalyst's surface was now examined in Part II<sup>9</sup>, with a conclusion that adsorbed hydrogen atoms exert an appreciable effect upon $\xi(s)$'s; with allowance for the latter, the $\xi(s)$'s were determined by fitting them to the experimental results of Zur Strassen<sup>11</sup> and Turkevich, Schissler and Irsa<sup>12</sup>. The present Part is devoted to derive the relation between $u$ and $Y$ and that between $Y$ and $P^H$ from the revised $\xi(s)$'s over an extended temperature range, inclusive of that of the above experiment of Twigg and Rideal in order to explain the observations quantitatively on the one hand and to find some criterion for discriminating between the mechanisms on the other hand.

<sup>9</sup> The equilibrium fraction $u$ is defined as $u=n^{PD}/n^{PD}_e$, where $n^{PD}$ is the amount of PD molecules present and $n^{PD}_e$ is the particular value of $n^{PD}$ at equilibrium of the reaction $P_2+D_2=2PD$ of the hydrogen existing.
Theory of Hydrogenation of Ethylene on Metallic Catalysts

Derivation of the Relations

The relation between $u$ and $Y$ has been given by Eq. (23.4) of Part I on the basis of the associative mechanism ignoring the isotopic difference of rates as

$$u = \frac{\exp\left(-\int_{Y}^{u} \frac{dY}{Y(1-Y)} \right) \int_{Y}^{u} y_i (1-y_i) \exp\left(\int_{Y}^{u} \frac{dY}{Y-y_i} \right) dY}{y_i (1-y_i) \exp\left(\int_{Y}^{u} \frac{dY}{Y-y_i} \right) dY} \quad (3)$$

for the initial condition $Y=1$, where $y_i$ is the atomic fraction of deuterium of adsorbed hydrogen atoms.

The $y_i$ in (3) must be given as a function of $Y$ for arriving at the relation between $u$ and $Y$ in question. We have from Eqs. (7.9) and (4.5) of Part I

$$n^Y(X) = 2/3 \cdot (y_i - x) \bar{v}(I) , \quad n^Y(Y) = 2 (y_i - Y) \bar{v}(Ib) \quad (4. E), (4. H)$$

and by Eqs. (4.8) there for the deuterium atomic fraction $x$ in CH$_a(a)$ and $y_i$,

$$X = \frac{6 \bar{v}(Ia)}{6 \bar{v}(Ia) + \bar{v}(II)} + \frac{y_i \bar{v}(II)}{6 \bar{v}(Ia) + \bar{v}(II)} , \quad (5. E)$$

$$y_i = \frac{X \cdot \frac{4 \bar{v}(Ia) \bar{v}(II)}{6 \bar{v}(Ia) + \bar{v}(II)} + 2Y \bar{v}(Ib) + Z \bar{v}(III)}{4 \bar{v}(Ia) \bar{v}(II) + 2 \bar{v}(Ib) + \bar{v}(III)} , \quad (5. H)$$

where $X$ or $Z$ is the deuterium atomic fraction in ethylene or ethane, $\bar{v}(s)'s$ or $\bar{v}(s)'s$ are the forward or backward rates of steps $s$'s ($s=I_a$, $I_b$, II, III) of the associative mechanism (2) subject to the steady condition*)

$$V_s = \bar{v}(s) - \bar{v}(s) , \quad s = I_a, I_b, II, III , \quad (6)$$

and $V_s$ is the steady rate of the catalyzed hydrogenation. The $\bar{v}(s)'s$ and $\bar{v}(s)'s$ are expressed in terms of $\bar{v}(s)'s$ by Eq. (2.12) of Part I, as

$$\bar{v}(I_a) = \bar{v}(I_a) , \quad \bar{v}(I_b) = \bar{v}(I_b) , \quad \bar{v}(II) = \bar{v}(II) , \bar{v}(III) = \bar{v}(III) \quad (7. I_a) \quad (7. I_b) \quad (7. II) \quad (7. III)$$

where $\Gamma$ is the BOLTZMANN factor of the affinity of the hydrogenation and $\bar{r}(H)$, $\bar{r}(C,H)_{I_a}$ or $\bar{r}(C,H)_{I_b}$ is the relative activity respectively of the intermediate H (a), C$_2$H$_4$(a) or C$_2$H$_4$(a) involved in (1), referred to its activity at its equilibrium**

*) Eq. 2.2 of Part I (Ref. 1).

**) The equilibrium of C$_2$H$_5$(a) for instance is that C$_2$H$_5$(a) = C$_2$H$_4$ + 1/2 H$_2$. 

--- 189 ---
with the reactants, \textit{i.e.} ethylene and hydrogen. We have from (6) and (7)
\[ V_s = \xi(I_a)(1 - \Gamma(C_2H_6)) = \xi(I_b)(1 - \Gamma(H)) \]
\[ = \xi(II)(\Gamma(H)\Gamma(C_2H_6) - \Gamma(C_2H_6)) = \xi(III)(\Gamma(H)\Gamma(C_2H_6) - \Gamma) . \quad (8) \]

It has been shown in Part I\textsuperscript{0} that \( \Gamma \) is extremely small compared with unity at the experimental conditions in question and that it follows from \( \Gamma \) less than unity in general that
\[ V_s > 0 \]
and
\[ 1 > \Gamma(C_2H_6), \Gamma(H), \Gamma(C_2H_6) > 0 . \quad (9) \]

It has further been shown on the basis of the revised \( \xi(s)'s \)\textsuperscript{0} with reference to the experimental condition of Twigg and Rideal\textsuperscript{2}, that\textsuperscript{0} \( \xi(I_a) \) is practically infinite compared with other \( \xi(s)'s \), hence with \( V_s \) according to (8) and (9), and that\textsuperscript{0} \( \Gamma \xi(III) \) or \( \bar{\nu}(III) \) according to (7, III) is completely negligible compared with all other \( \bar{\nu}(s)'s \) and \( \bar{\nu}(s)'s \), \textit{i.e.}
\[ \xi(I_a) \gg \xi(s'), s' = I_b, II, III ; \xi(I_a) \gg V_s ; \quad (10. \xi), (10. V) \]
\[ \bar{\nu}(II) \ll \bar{\nu}(III), \bar{\nu}(III) \ll \bar{\nu}(s''), \bar{\nu}(s'), s'' = I_a, I_b, II . \quad (10. III) \]

It follows now from (10. \( \xi \)), (7) and (9), that \( \bar{\nu}(I_a) \) is infinitely greater than all \( \bar{\nu}(s')'s \) and \( \bar{\nu}(s')'s \), hence (5) is simplified, besides by ignoring \( \bar{\nu}(III) \) according to (10. III), as
\[ x = X , \quad (11. x) \]
\[ y_1 = \frac{X\bar{\nu}(II) + 3Y\bar{\nu}(I_b)}{\bar{\nu}(II) + 3\bar{\nu}(I_b)} . \quad (11. y) \]

Substituting \( x \) and \( y_1 \) from (11) into (4), we have
\[ n^xX = 2(Y-X)F\bar{\nu}(I_b) , \quad n^xY = 2(X-Y)F\bar{\nu}(I_b) , \quad (12. X), (12. Y) \]
where
\[ F = \frac{\bar{\nu}(II) + 3\bar{\nu}(I_b)}{\bar{\nu}(II) + 3\bar{\nu}(I_b)} \quad (12. F) \]

hence
\[ Y-X = \exp \left\{ - \int_0^t 2F\left( \bar{\nu}(I_b)\frac{n'}{n^x} + \bar{\nu}(I_b) \right) \frac{dt}{n'} \right\} \quad (13) \]

for the initial condition \( X=0 \) and \( Y=1 \) at \( t=0 \), where \( t \) is the time. The \( n'/n^x \) there keeps constant at 1/2 throughout for the catalyzed interaction of equimolecular ethylene and deuterium in this case. Substituting \( Y-X \) from (13) into (12. Y), we have
Theory of Hydrogenation of Ethylene on Metallic Catalysts

\[ n''Y = -2F\bar{v}(I_b)\exp\left\{-\int_0^t 2F\left(\tilde{v}(I_b)\frac{n''}{n''} + \bar{v}(I_b)\right)\frac{dt}{n''}\right\}, \quad (14. x) \]

which gives on integration with reference to the above initial condition

\[ 1 - Y = 2\int_0^t F\bar{v}(I_b)\exp\left\{-\int_0^t 2F\left(\tilde{v}(I_b)\frac{n''}{n''} + \bar{v}(I_b)\right)\frac{dt}{n''}\right\} \frac{dt}{n''} \quad (15. a) \]

or on substitution of \( n''Y \) from (4. H)

\[ y_1 - Y = -F \exp\left\{-\int_0^t 2F\left(\tilde{v}(I_b)\frac{n''}{n''} + \bar{v}(I_b)\right)\frac{dt}{n''}\right\}. \quad (15. b) \]

The variable of integration is now changed for the sake of an expedient numerical calculation, noting that \( n'' \) is proportional to \( P'' \) and that \( 2V_s = \frac{d\ln n''}{dt} \) by definition i.e.

\[ \frac{d\ln n''}{dt} \equiv \frac{2V_s}{n''} = -\frac{d\ln P''}{dt}, \]

hence

\[ 2\frac{dt}{n''} = -d\ln P''/V_s. \quad (16) \]

Substituting \( dt/n'' \) from (16) into (15), we have

\[ 1 - Y = \int_{P''}^0 \frac{F\bar{v}(I_b)}{V_s} \exp\left\{-\int_{P''}^t \frac{F}{V_s}\left(\tilde{v}(I_b)\frac{n''}{n''} + \bar{v}(I_b)\right) d\ln P''\right\} d\ln P'', \quad (17. a) \]

\[ y_1 - Y = -F \exp\left\{-\int_{P''}^t \frac{F}{V_s}\left(\tilde{v}(I_b)\frac{n''}{n''} + \bar{v}(I_b)\right) d\ln P''\right\}, \quad (17. b) \]

where \( P'' \) is the initial value of \( P''. \)

Eqs. (17) enable us to compute the correlative values of \( Y, y_1, \) and \( P'' \) varying with the progress of hydrogenation and these values decide the relation between \( u \) and \( Y, \) when substituted into (3). The rates \( \tilde{v}(I_b), \bar{v}(I_b), \tilde{v}(II), \bar{v}(II) \) and \( V_s \) in (17) are given as functions of \( P'' \) as follows. We have \( \tilde{r}(C_2H_4) \approx 1 \) by (10. V) and (8), so that (8) is reduced, by (10. III) and (7), to the form

\[ V_s = \tilde{v}(I_b)(1 - \tilde{r}(H)^2) = \tilde{v}(II)\tilde{r}(H) - \tilde{r}(C_2H_4) = \tilde{v}(III)\tilde{r}(H)\tilde{r}(C_2H_4). \quad (18) \]

\( V_s, \tilde{r}(H) \) and \( \tilde{r}(C_2H_4) \) are calculated by (18) from \( \tilde{v}(s)'s \) revised in Part II as\(^*\)

\[ \tilde{v}(I_b) = 2.0573 \times 10^{-18} \times 10^{-1354.6/T} \times P''(P''^{0.520})^{1.2} \rho, \]

\[ \tilde{v}(II) = 2.4687 \times 10^{-20} \times 10^{-220.12/T} \times (P'')^{1.2} \rho, \]

\(^*\) The present calculation is based on the value \(-220.12/T\) in the expression of \( \tilde{v}(II) \), which is to be replaced by somewhat a larger value \(-165.4/T\). The result from the latter corrected value will be reported in a later paper, although the conclusion is essentially unchanged as expected from the similar variation added at the proof.
Journal of the Research Institute for Catalysis

\[ \mathcal{R} \text{(III)} = 2.4012 \times 10^{-25} \times 10^{-25} \times P^P \rho, \]

hence \( \tilde{v}(s)'s \) and \( \tilde{v}(s)'s \) by (7) as functions of \( T \) and \( P^P \), where \( \rho \) is a common factor, which is of less importance in the present calculation of the quantities, which depend solely on the relative magnitudes of \( \tilde{v}(s), \tilde{v}(s) \) and \( V_s \) as seen from (17) and (3), hence on those of \( \mathcal{R}(s)'s \) as shown in Part II\(^p\).

**Results**

The values of \( Y \) and \( y_1 \) calculated as above at different \( P^P = P^E \) decreasing

**Table 1.** Correlative variation of \( Y, y_1 \) and \( P^P = P^E \) during the catalyzed interaction of \( \text{C}_2\text{P}_4 \) with \( \text{D}_2 \) in the presence of Ni-catalyst.

</table>

from its initial value 10 mmHg at different temperatures are given in Table 1 and the $Y,P^e$-relation is shown in Fig. 1.

Table 2 and Fig. 2 show the $1-u,Y$-relation derived from the result of Table 1 by (3). We see from Fig. 2 that the curves of $1-u$ versus $Y$, not quite linear as in the experiment of Twigg and Rideal, rise with decrease of temperature upwards, increasing the height $1-u$ at $Y=1$ up to ca. 50°C and then, approximately fixing the latter height, draws the point on the abscissa toward the ordinate $Y=1$, adhering to it at lower temperatures.

The above behavior of the theoretical curve with temperature is approximately in agreement with the experimental results of Twigg and Rideal.\(^{3}\)
Theory of Hydrogenation of Ethylene on Metallic Catalysts

the respects that it remains more or less stationary between ca. 50 C and 150·C and that it turns down with increase of temperature above ca. 150 C, which was disregarded by these authors as the basis of their mechanisms. The theoretical curve runs thus quite differently at temperatures below 50 C from the constant straight line, which is required by the mechanisms proposed by these authors.

The above theoretical predictions are thrown to experimental tests by one of the present authors (I.M.).

Summary

Theoretical procedure developed in Part I and II of deriving rates of the catalyzed hydrogenation of ethylene and of reactions associated with it in terms of the characteristic rate functions $\xi(s)$'s relevant respectively to the constituent steps $s$'s of the associative mechanism of the catalyzed hydrogenation was applied to follow the correlative variation of the equilibrium fraction $u$ (the fraction of PD present over that at equilibrium of the reaction $P + D \rightarrow 2PD$, where $P$ is protium), the deuterium atomic fraction $Y$ and the partial pressure of hydrogen in course of the catalyzed interaction of $C_3P_4$ with $D_2$ for the experimental condition of TWIGG and RIDEAL, where the initial partial pressures both of $C_3P_4$ and $D_2$ were 10 mmHg. The appropriate calculation was based on $\xi(s)$'s revised in Part II with allowance for the effect of adsorbed hydrogen atoms.

The theoretical conclusion from the associative mechanism thus derived on the relation between $u$ and $Y$ was found in concordance with the experimental results of TWIGG and RIDEAL over the temperature range of their observation but to deviate distinctly at lower temperatures from that expected from their mechanisms, thus providing a criterion for experimentally discriminating the associative mechanism from their mechanisms.

Acknowledgement

The present authors wish to express their profound thanks to Miss Masako HORIUTI and Messrs. Takeshi SAITO, Shizuka OTSU and Motomasa TAKAHASHI for their collaboration in carrying out the complicated numerical calculations.
