HETEROGENEITY EFFECTS IN ADSORPTION KINETICS OF GAS MIXTURES

By

M. Jaroniec*)

(Received September 25, 1979)

Abstract

The fundamental differential equation of kinetics of gas adsorption has been formulated for adsorption of multicomponent gas mixtures on energetically heterogeneous solid surfaces. This approach leads to a simple dependence for two arbitrary adsorbing components; namely, the ratio of surface coverages is a simple power function of the ratio of partial pressures. Many experimental data available from the literature fit very well this relationship.

Introduction

The kinetics of adsorption process is determined by rates of adsorption, desorption and diffusion. In the case of adsorption from gaseous phase the diffusion is generally sufficiently fast that it plays no role in the determination of the kinetics. Thus the diffusion effects may be neglected.

Many attempts have been made to describe the adsorption kinetics of single gases on homogeneous surfaces.1–6 Only a few of them consider the adsorption kinetics of gas mixtures.3,7 However, for the case of a heterogeneous surface, the kinetics of monolayer adsorption is usually discussed at low surface coverages or at surface coverages close to unity.2,3,8 In the other cases, the adsorption kinetics is modelled by the empirical equations. The recent studies of Wojciechowski et al.9,10 lead to the expressions describing kinetics of monolayer adsorption of single gases on heterogeneous surfaces in the whole region of the surface coverages.

In this paper we propose an approach to the kinetics of monolayer mixed-gas adsorption on heterogeneous solid surfaces, basing on the theory of mixed-gas adsorption11–21 and partially applying the results obtained by Wojciechowski et al.9,10 for adsorption kinetics of single gases.

*1 Department of Theoretical Chemistry, Institute of Chemistry, M. Curie-Skłodowska University, 20031 Lublin, Poland.
Equation of sorption rate

Let us consider a $n$-component gas mixture on a heterogeneous surface by neglecting the lateral interactions and assuming identical molecular area for all components. Such assumptions occur frequently in the theory of gas adsorption. The fundamental equation of kinetics of gas adsorption may be formulated as follows:

$$\frac{dN_{i(n),l}}{dt} = k_i^a p_i (M_l - \sum_{i=1}^{n} N_{i(n),l}) - k_i^d N_{i(n),l}$$  

(1)

where the subscripts $i$ and $l$ concern the $i$-th component and $l$-th surface patch, respectively; $M_l$ is the number of adsorption sites on the $l$-th surface patch; $N_{i(n),l}$ is the number of adsorbed molecules of the $i$-th component on the $l$-th surface patch; $p_i$ is the partial pressure of the $i$-th component; $k_i^a$ and $k_i^d$ are adsorption and desorption constants for the $i$-th component and $l$-th surface patch. According to the treatment each adsorption site is characterized by a vector of activation energies of all components. Then, the total number of adsorbed molecules of the $i$-th component on the whole surface is equal to

$$N_{i(n)} = \sum_{l=1}^{L} N_{i(n),l}$$  

(2)

where $L$ is the number of surface patches. However, the rate equation for the whole surface is

$$\frac{dN_{i(n)}}{dt} = p_i \sum_{l=1}^{L} k_i^a (M_l - \sum_{i=1}^{n} N_{i(n),l}) - \sum_{l=1}^{L} k_i^d N_{i(n),l}$$  

(3)

Replacing in Eq. (3) the symbols $N_{i(n),l}$ and $N_{i(n)}$ by the relative surface coverages, we obtain:

$$\frac{dV_{i(n)}}{dt} = p_i \sum_{l=1}^{L} k_i^a h_l (1 - \theta_{i(n)}) - \sum_{l=1}^{L} k_i^d h_l \theta_{i(n)}$$  

(4)

where $\theta_{i(n)} = N_{i(n),l}/M_l$ and $V_{i(n)} = N_{i(n)}/M$ are monolayer surface coverages of the $i$-th component from $n$-component gas mixture on homogeneous and heterogeneous surfaces, respectively; $M = \sum_{l=1}^{L} M_l$ is the total number of adsorption sites; $h_l = M_l/M$; and $\theta_{i(n)} = \sum_{l=1}^{L} \theta_{i(n)}$. Now we apply in Eq. (4) a similar approximation to that, which has been introduced by Wojciechowski et al. In the case of adsorption kinetics of $n$-component gas mixtures this approximation may be expressed by means of two equations:
Heterogeneity Effects in Adsorption Kinetics of Gas Mixtures

\[ \sum_{i=1}^{L} k_{it} h_i (1 - \theta_{(an)}) = \bar{k}_{it} (1 - V_{(an)}) \cdot X(1 - V_{(an)}) \] \hfill (5)

and

\[ \sum_{i=1}^{L} k_{it} h_i \theta_{(an)} = \bar{k}_{it} V_{(tn)} \cdot Y(V_{(tn)}) \] \hfill (6)

Simulations for adsorption kinetics of single gases have shown that in practice \( X \) and \( Y \) are well represented by simple power functions. Thus, in the case of mixed-gas adsorption the functions \( X \) and \( Y \) may be expressed by:

\[ X(1 - V_{(an)}) = (1 - V_{(an)})^{w} \; ; \; \; w > 0 \] \hfill (7)

and

\[ Y(V_{(tn)}) = (V_{(tn)})^{m_i} \; ; \; \; m_i > 0 \] \hfill (8)

Applying Eqs. (5)-(8) in Eq. (4) we get

\[ \frac{dV_{(an)}}{dt} = \bar{k}_{it} p_i (1 - V_{(an)})^{w+1} - \bar{k}_{it} (V_{(tn)})^{m_i+1} \] \hfill (9)

At the equilibrium Eq. (9) generates the following adsorption isotherm:

\[ (V_{(an)})^{m_i+1}/(1 - V_{(an)})^{w+1} = (\bar{k}_{it}/\bar{k}_{i})p_i \] \hfill (10)

The constants \( w \) and \( m_i \) may be treated as heterogeneity parameters. For many adsorption systems these parameters are approximately identical, \( i.e., \ w = m_i \) and then we get

\[ \frac{dV_{(an)}}{dt} = \bar{k}_{it} p_i (1 - V_{(an)})^{w+1} - \bar{k}_{it} (V_{(tn)})^{m_i+1} \] \hfill (11)

and

\[ V_{(an)} = \frac{c_i (p_i)^r}{1 + \sum_{j=1}^{n} c_i (p_i)^r} \] \hfill (12)

where

\[ r = (w+1)^{-1} \; \text{and} \; c_i = (\bar{k}_{it}/\bar{k}_{i})^r \] \hfill (13)

The adsorption isotherm (12) is very similar to the equation of adsorption isotherm of single gases, which has been obtained by Sips.

The presence of a precursor state

The generalization of the results of Crickmore and Wojciechowski, concerning the presence of a precursor state, to the mixed-gas adsorption gives the following rate equation:

\[ \sum_{i=1}^{L} k_{it} h_i (1 - \theta_{(an)}) = \bar{k}_{it} (1 - V_{(an)}) \cdot X(1 - V_{(an)}) \] \hfill (5)
where $M_p$ is the initial number of adsorption sites in the preadsorbed state, $M$ is the total number of adsorption sites, and $V_{i\to n}(n)$ is the adsorption isotherm for the precursor. Let us consider two equations for $V_{i\to n}(n)$; Henry's and Langmuir's isotherms. In the first case we get

$$
\frac{dV_{i\to n}}{dt} = \frac{k_t M_p}{M} [V_{i\to 0}(p_1, p_2, \ldots, p_n)]^{w} - k_t^i (V_{i\to n})^{m+1} \quad (14)
$$

At the equilibrium Eq. (15) generates the classical Freundlich isotherm at low adsorbate pressures:

$$
\frac{dV_{i\to n}}{dt} = \frac{k_t M_p}{M} (K_t^n p_i^w) - k_t^i (V_{i\to n})^{m+1} ; \quad w^0 > 0
$$

$$(15)
$$

where $K_t^n$ is the Henry's constant for $i$-th component. The application of the Langmuir isotherm in Eq. (14) leads to the following rate equation:

$$
\frac{dV_{i\to n}}{dt} = \frac{k_t M_p}{M} \left[ \frac{a_i p_i}{1 + \sum_{j=1}^{n} a_j p_j} \right]^{w} - k_t^i (V_{i\to n})^{m+1}
$$

$$(17)
$$

which generates the following mixed-gas adsorption isotherm:

$$
V_{i\to n} = \frac{k_t^i M_p}{k_t^0 M} \left[ \frac{a_i p_i}{1 + \sum_{j=1}^{n} a_j p_j} \right]^{w/\omega(m+1)}
$$

$$(18)
$$

If $(k_t^i M_p)/(k_t^0 M) = 1$ we get from Eq. (18) the generalized Freundlich adsorption isotherm for gas mixtures,

$$
V_{i\to n} = \left[ \frac{a_i p_i}{1 + \sum_{j=1}^{n} a_j p_j} \right]^{r_i} ; \quad r_i = \omega^0/(m+1)
$$

$$(19)
$$

which has been earlier obtained by Jaroniec.

Analysis of adsorption isotherm (12)

The most interesting equation of adsorption isotherm for gas mixtures is Eq. (12). The ratio of two partial isotherms $V_{i\to n}$ and $V_{j\to n}$ for $i \neq j$, given by Eq. (12), is equal to:

$$
V_{i\to n}/V_{j\to n} = (c_i/c_j)^{(p_i/p_j)^{r}}
$$

$$(20)
$$

Eq. (20) may be rewritten in this simpler form:

$$
V_{i\to n}/V_{j\to n} = (c_i/c_j)^{p_i/p_j^{r}}
$$

$$(21)
$$
Heterogeneity Effects in Adsorption Kinetics of Gas Mixtures

\[ V_{ij} = c_{ij} \cdot p_{ij} \]  

(21)

or

\[ \ln V_{ij} = \ln c_{ij} + r \ln p_{ij} \]  

(22)

where \( V_{ij} = V_{i(n)} / V_{j(n)} \), \( c_{ij} = c_i / c_j \) and \( p_{ij} = p_i / p_j \).

Now let us discuss the constant \( c_{ij} \) more exactly. According to the papers\(^{9,10}\) the constants \( k_t \) and \( k_1 \) may be expressed in the form:

\[ k_t = k_1^t \exp(-E_t / RT) \]  

(23 a)

and

\[ k_1 = k_1^1 \exp(-E_1 / RT) \]  

(23 b)

where \( E_t \) and \( E_1 \) are average activation energies for adsorption and desorption, respectively, whereas, \( K_t \) and \( K_1 \) are pre-exponential factors. Using the definition of \( c_{ij} \) and Eqs. (23 a) and (23 b), we obtain:

\[ c_{ij} = \left[ \frac{K_t^i K_1^j}{K_t^j K_1^i} \right]^r \exp \left[ \frac{r(E_t^i - E_t^j) - r(E_1^i - E_1^j)}{RT} \right] \]  

(24)

As it is known, that the difference between \( E_t^i \) and \( E_t^j \) is equal to the adsorption energy \( E; \) thus

\[ (E_t^i - E_t^j) - (E_t^j - E_t^j) = E_i - E_j = E_{ij} \]  

(25)

and

\[ c_{ij} = (K_t^i K_1^j)^r \exp(rE_{ij}/RT) = (c_{ij})^r \]  

(26)

From Eq. (22) the difference of the isosteric heats of adsorption, \( Q_{i(n)} \) and \( Q_{j(n)} \), may be evaluated, it is

\[ Q_{i(n)} = Q_{i(n)} - Q_{j(n)} = RT^2(d\ln p_{ij}/dT)v_{i(n)}, v_{j(n)} = -RT^2(d\ln c_{ij}^r/dT) \text{ for } r(T) = \text{const} \]  

(27 a)

and

\[ Q_{i(n)} = -RT^2(d\ln c_{ij}^r/dT) + RT^2[d(1/r)/dT]\ln V_{ij} \]  

for \( r(T) \neq \text{const} \)  

(27 b)

After a few simple manipulations in Eqs. (27 a) and (27 b) we get

\[ Q_{i(n)} = -RT^2[d\ln(K_t^i K_1^j)/dT] + E_{ij} \text{ for } r(T) = \text{const} \]  

(28 a)

and

\[ Q_{i(n)} = -RT^2[d\ln(K_t^i K_1^j)/dT] + E_{ij} + RT^2[d(1/r)/dT]\ln V_{ij} \]  

for \( r(T) \neq \text{const} \)  

(28 b)
For chemically similar components \(i\) and \(j\), the product \(K_{ji} K_{ij}^*\) is practically temperature independent, \(i.e.,\)

\[
K_{ji}^* (T) \cdot K_{ij}^* (T) = \text{const}
\]  

Then

\[
Q_{ij(n)} = E_{ij} \text{ for } r(T) = \text{const}
\]  

The exact analysis of the function \(r(T)\) leads to the following expression:\n
\[
r(T) = \frac{1}{\hat{r}} RT \quad \text{where } \hat{r} = \text{const}
\]  

Using in Eq. (28 b) the assumptions (29) and (31) we obtain

\[
Q_{ij(n)} = E_{ij} = (1/\hat{r}) \ln V_{ij(n)}
\]  

The selectivity coefficient \(s_{ij}\), defined by the equation:\n
\[
s_{ij} = p_{ji} V_{ij(n)},
\]  

for adsorption isotherm (12) is equal to:

\[
s_{ij} = V_{ij(n)}^{(r'-1)/r} c_{ij}^*
\]  

Taking into account the relationships (27 a) and (27 b) we have

\[
d \ln s_{ij}/dT = -(1/RT^2) Q_{ij(n)} \text{ for } r(T) = \text{const}
\]  

and

\[
d \ln s_{ij}/dT = -(1/RT^2) Q_{ij(n)} + (1/\hat{r} RT^2) \ln V_{ij(n)}
\]  

The last equations after integration give:

\[
\ln s_{ij} = Q_{ij(n)}/Rt + \text{const}
\]  

and

\[
\ln s_{ij} = Q_{ij(n)}/RT - \ln V_{ij(n)}/(RT \hat{r}) + \text{const}
\]  

**Applications**

To demonstrate the well applicability of the adsorption isotherm (12), the experimental data available from the literature,\(^{26-30}\) concerning the mixed-gas adsorption, have been taken to compute the best-fit straight lines according to Eq. (22). These data have been measured for adsorption of simple hydrocarbons on different carbon adsorbents, silica gel and adsorption of nitrogen on cesium iodide (Table 1 contains some informations about the adsorbent samples). However, in Table 2 the parameters of Eq. (22), \(i.e.,\)

\[
r, c_{ij} \text{ and the standard deviation}
\]

\[
SD = \left\{ \frac{\sum_{j=1}^{M} [\ln V_{ij(\text{exp})(j)}^\text{cal} - \ln V_{ij(\text{exp})(j)}^\text{cal}]/(M-2) \right)^{1/2}
\]
