THE NUCLEOTIDE SEQUENCE OF THE GENES,
fanE AND *fanF*, OF
Escherichia coli K99 FIMBRIAE.

Eriko ONO¹, Martin F. LAVIN², Masaharu NAIKI^{1,3,4}

(Accepted for Publication: January 7, 1991)

K99 fimbriae of enterotoxigenic *Escherichia coli* consist of eight different subunits. A major subunit called fimbrillin forms fimbrial structure and a minor subunit called adhesin localizes at the tip of fimbriae and recognizes host receptor ganglioside. Within this eight gene cluster, *fanE* and *fanF* have not yet been sequenced. In this study, *fanE* and *fanF* genes were sequenced by analyzing several DNA fragments produced by endonuclease or exonuclease digestion. The *fanE* gene encoded 227 amino acids containing 20 amino acids of signal peptide starting from GTG (valine) and showed a homology to *fanA-fanB*. The *fanF* gene encoded 271 amino acids containing 20 amino acids of signal peptide starting from ATG (methionine) and showed homologies to the *fanD* gene, fimbrillin gene of F41, adhesin gene of P fimbriae (*papG*) and adhesin gene of Type 1 fimbriae (*fimH*). E and F subunits had fifteen and fourteen hydrophobic domains, respectively, which periodically appeared possibly forming a hydrophobic region.

Key words: Enterotoxigenic *Escherichia coli*, K99 fimbriae, *fanE* and *fanF* DNA sequence, hydrophobic domain.

INTRODUCTION

Enterotoxigenic *Escherichia coli* possessing K99 fimbrial antigen are frequently isolated from newborn calves, piglets, and lambs suffering from diarrhea²¹). It is known that fimbriae are important as an adhesive and colonization factor of bacteria on the mucosal surface of the small intestine in the first stage of infection^{1,5,6}). Fimbriae have been classified by their antigenicity and subunit molecular weight. The fimbriae are composed of fimbrillin which forms main part of fimbriae and adhesin which recognizes carbohydrate receptors on the surface of host cells^{13,23,24}).

The K99 fimbrial gene cluster named *fanA* to *fanH* encodes eight different subunits¹⁵. The nucleotide sequences of *fanA*, *fanB*, *fanC*, *fanD*, *fanG*, and *fanH* have already been published^{16,117,19}. The functions of these subunits were analyzed and it has been established that *fanC* encodes fimbrillin¹⁶, *fanA* and *fanB* encode regulatory proteins which control expression of fimbriae^{17,20}, *fanD* encodes platform protein¹⁹ and *fanG* and *fanH* encode minor subunits¹⁸. However there is no available information about the gene encoding adhesin. Since it is highly possible that either *fanE* or *fanF* encodes this receptor protein, in this study, the complete gene structure of *fanE* and *fanF* were determined.

MATERIALS AND METHODS

Host cells and plasmid vector: As a host bacterial strain, JM109 or JPA101 was used, and as a vector, pUC19²⁶ or BLUESCRIPT²² was prepared for isolation of single strand DNA. Isolation of plasmid DNA, agarose gel electrophoresis, and transformation were performed according to conventional methods²². Transformants were cultured in LB media or 2YT media²² with 50 μ g/ml of ampicillin.

Endonuclease and the other enzymes: *Ava*I, *Bam*HI, *Bgl*II, *Cla*I, *Hinc*II, *Kpn*I, *Pst*I, *Xba*I, exonuclease III, S1 nuclease, and *E. coli* DNA polymerase I (Klenow fragment) (TAKARA Co. Ltd., Kyoto, Japan) were used to prepare several DNA fragments from an original plasmid pFK99 (pUC19). T4 ligase (NIPPON GENE Co. Ltd., Toyama, Japan) was used for ligation.

Sequence procedure: Single strand DNA was prepared according to SEQUENASE protocol or Biochemical research products: Protocol and application committed to science worldwide (Promega protocol). 6% polyacrylamide gel containing 7M urea was used in the electrophoresis for sequencing. Samples for sequencing were prepared using SEQUENASE Ver. 2.0 kit (TOYOBO Co. Ltd., Osaka, Japan). pFK99 (pBR322) which contained K99 fimbrial gene cluster (*fanA* to *fanH*) were kindly supplied by Dr. de Graaf, Vrije University, Amsterdam, the Netherlands. *Bam*HI-*Bam*HI fragment encoding the whole K99 gene cluster of pFK99 (pBR322)²⁵ was cloned into pUC19 vector (pFK99(pUC19)) and used for subcloning (Fig. 1).

Preparation of subclones containing fanE and fanF: Subclones including *fanE* and *fanF* genes were prepared (Fig. 1). *Kpn*I-*Ava*I fragment isolated after agarose gel electrophoresis using GENE CLEAN™ Kit (FUNAKOSHI Co. Ltd., Tokyo, Japan) was treated with Klenow enzyme and inserted again into pUC19 cleaved with *Kpn*I and *Hinc*II, to make pFK99KA. pFK99AH (*Ava*I-*Hinc*II, fragment) and pFK99KC (*Kpn*I-*Cla*I fragment) were prepared by using each particular restriction enzyme site. pFK99 (KK3.3R) was prepared from pFK99 (pUC19) by using the *Kpn*I site. Digestion of pFK99(KK3.3R) with exonuclease III was performed at 37°C and at 30 sec intervals, samples of partially digested DNA were taken according to Promega protocol. After cloning, DNA length was checked by agarose gel electrophoresis and 15

Fig. 2. Primary sequence of *fanE* and *fanF* genes. An arrow shows a position cleaved by digestion with signal peptidase I. -35 and -10 indicate promoter sequences. S. D. means ribosome-binding site. Stopping codon is indicated by ***.

Characterization of E and F subunits: According to computer analysis, the E subunit had partial homologies to the B, C, and D subunits of K99 fimbriae in its amino acid Sequence. The F subunit was partially homologous to the G adhesin subunit of P fimbriae, C and H subunits of K99 fimbriae. The hydrophobic character of these proteins are shown in Fig. 3. Fifteen and fourteen hydrophobic domains appeared in the E and F subunits, respectively. Particularly notable are the hydrophobic peaks of *fanE* which periodically appeared.

DISCUSSION

Various kinds of fimbrial genes were cloned from *Escherichia coli* or other bacterial cells. Among them, fimbrial genes of P^(2,3,4,11,12,14) and Type 1^(7,8,9) were well

Fig. 3. Hydrophobic character of E and F subunits. Signal peptide is removed at a position indicated by an arrow. Hydrophobic peaks are indicated by boxes.

analyzed. It is known that the fimbrial gene and amino acid sequence of the products have some homologies.

Roosendaal et al. have reported on the K99 gene cluster and indicated that *fanC* encodes fimbrillin of K99 antigen (16.5 KDa)¹⁶⁾. The A subunit (11.0 KDa)¹⁷⁾, B subunit (10.8 KDa)¹⁷⁾, D subunit (84.5 KDa)¹⁹⁾, G subunit (16.9 KDa)¹⁸⁾, and H subunit (16.3 KDa)¹⁸⁾ have been reported to be homologous in their nucleotide sequences. In the analysis of hydrophobicity, the periodic appearance of hydrophobic domain was detected.

In this study, *fanE* and *fanF* were sequenced for the first time. The starting codon of *fanE* was GTG, coding for valine. This starting codon is unique among the fimbrial genes of which uncleotide sequences have been reported. It was found that *fanD*, *fanE*, and *fanF* overlapped each other in the structural gene regions. A similar overlapping was reported in *fanG* and *fanH* of K99 fimbriae¹⁸⁾. In addition, the *fanF* had homologies to the genes encoding adhesin of P and Type 1 fimbriae. In contrast, *fanE* showed a homology only to the *fanA*–*fanB* connecting region. Thus, the E subunit seems a very unique subunit within the K99 fimbriae. Regarding the hydrophobic character of *fanE* and *fanF*, fifteen and fourteen peaks were detected, respectively. In addition, the peaks of *fanE* appeared periodically, indicating that those formed the hydrophobic part of the E subunit.

At present it is not known which gene encodes K99 adhesin. However, it was found that the *fanF* had some homology to the adhesin gene of other fimbriae. Further analysis using mutants lacking *fanE* and *fanF* is necessary to determine the function of these subunits. Such experiments are now in progress.
