**ABSTRACT** The rhizoplane microorganisms of *Melastoma malabathricum*, distributing throughout the acid sulfate and peat soils of South Kalimantan, Indonesia, were investigated, using a soft gel media of N-free Winogradsky's mineral solution solidified with 0.3 % gellan gum. Two bacteria, *Sphingomonas rosa* EC-K013 and *Burkholderia cepacia* EC-K014 belonging to the subclasses of  $\alpha$ - and  $\beta$ -Proteobacteria, respectively, emerged in the nitrogen-free medium. Inoculation of *S. rosa* EC-K013 in the *M. malabathricum* seedlings grown in N-free, 1/4 Hoagland's No. 2 medium (pH 3.0) resulted in better growth of the seedlings. In the soft gel medium, EC-K013 also stimulated the growth of a root-associated fungus, tentatively identified as *Nectria* sp. and a nitrogen-fixing, *Mesorhizobium* sp., suggesting that *S. rosa* plays an important role in promotion of microfloral development around the rhizosphere of some acidic soil-adapting plants.

**Key words:** Acid-sulfate soil, *Burkholderia cepacia*, *Melastoma malabathricum*, Rhizoplane bacterium, *Sphingomonas rosa*.

Many species of genus *Melastoma*, such as *M. malabathricum* L., are known to be Al-accumulators (Watanabe *et al.*, 1998a), and the adaptability of *Melastoma* spp. to very low pH acid-sulfate soils is mainly due to this property. *M. malabathricum*, distributing throughout Central and South Kalimantan, Indonesia, is a powerful pioneer shrub tree that is able to spread throughout the acid-sulfate soil regions. Since acid-sulfate soil with very low pH (2.5-3.5) has undergone strong leaching, such acid-tolerable plants must employ certain strategies to get nutrients, including N and P. *Melastoma* spp. are also known as ammonia-assimilating plants, preferring  $\text{NH}_4^+$  rather than  $\text{NO}_3^-$  as a nitrogen source (Watanabe *et al.*,

1998b). Bearing these facts in mind, the presence of free-living nitrogen-fixing bacteria on the rhizoplane of *M. malabathricum* is thought to be beneficial to their survival in acid-sulfate soils, due to the release of ammonia into the rhizosphere. Ammonia is very likely a key material in the adaptation of the *M. malabathricum* to acid-sulfate soil, not only as a nitrogen source but also as an inorganic base provided via nitrogen-fixation. So far during our field investigation in South and Central Kalimantan, free-living nitrogen-fixing, and/or pH-maintaining bacteria were frequently isolated from the rhizosphere of *M. malabathricum*. In this paper, we report an effective growth promoting activity of a sphingomonad from the rhizosphere toward the seedlings under N-starving and strongly acidic conditions to discuss further its ecological role in forming a tripartite with a nitrogen-fixing and a root-associated fungus.

## MATERIALS AND METHODS

### Screening and identification of rhizoplane bacteria

We used a gellan gum-base soft gel medium for the observation and evaluation of the microflora of rhizoplane nitrogen-fixing bacteria as described in our paper (Hashidoko *et al.*, 2002). Bacteria obtained from root washings were purified on modified Winogradsky's medium (Winogradsky's mineral mixture, 0.5% mannitol, 0.005% yeast extract and 2% agarose). For identification, 16S rRNA gene sequences were determined and homology searches conducted using the DDBJ BLASTN DNA database (<http://www.ddbj.nig.ac.jp/E-mail/homology-j.html>). All of the DNA template for PCR amplification of the 16S rRNA gene regions was prepared using Isoplant II DNA extraction kit (Wako Pure Chemical Industries, Osaka, Japan). For DNA amplification, we used the PCR kit Gene Taq (Nippon Gene, Toyama, Japan) or HotStarTaq (Quiagen, Valencia, USA) according to its instruction protocol. The amplified

DNA fragments were directly sequenced using the BigDye® Terminator v3.1 Cycle Sequencing Kit (Applied Biosystems, Foster City, USA) with several sequencing primers under the following conditions: 1 cycle at 96°C for 2 min and 25 cycles of 96°C for 30 s, 50°C for 15 s, 60°C for 4 min by using the ABI PRISM® 310 Genetic Analyzer (Applied Biosystems). The resultant DNA sequences were assembled and then searched for homology on the BLASTN searching system on a DNA database.

#### Identification of rhizosphere fungi

Fungi were identified by means of partial sequence determination of 5.8S and 18S rRNA genes and the ITS regions between them. After the chromosomal DNA was obtained, ITS regions were amplified with PCR using the ITS1 forward (5'-TCCCGTAGGTGAACCTGCGC-3') and ITS4 reverse (5'-TCCTCCGCTTATTGATATGC-3') primers that are specific for eukaryotic microorganisms and give rise to a 450 bp PCR product (Kretzer & Bruns, 1999; Sugita & Nishikawa, 2003). The fungal mycelium growing on the PD agar plate was inoculated to new PD agar plate and incubated at 23°C for 3–7 days, and the myceria on the plate was directly scraped with a loop and then inoculated separately or together with *S. rosa* EC-K013 to the N-free soft gel medium. DNA sequence determination followed by its homology search was performed as described above for bacteria.

#### Seedling preparations and inoculation assay

*M. malabathricum* used for microfloral investigation in the rhizoplane were collected from the ridge of a sulfate acid soil paddock at Serapatbaru in Southern Kalimantan, and from the ridge of a peat soil field at Kalamangan in Central Kalimantan, respectively. For plant growth, we used an EYELA LTI 600 SD thermo-controlling incubator equipped with red and blue light emitting diodes (EYELA LED-red/blue, 40/10 per board of 30 x 30 cm<sup>2</sup> width) as illuminants. A bed volume of 50 ml vermiculite was poured into a tall-skirted Petri dish, and moistened with approximately 30 ml of a N-free 1/4 Hoagland's no. 2 solution, in which molybdenum trioxide (MoO<sub>3</sub>) was enhanced 50-fold and adjusted to pH 3.0.

Seeds collected from Central Kalimantan were sown in the autoclaved vermiculite bed moistened with the sterile N-free 1/4 Hoagland's no. 2 as described above, and incubated at 23°C under a 16-h light/8-h dark photoperiod. The *M. malabathricum* seedlings were prepared as follows: after the 50 ml vermiculite beds (wetted with the N-free 1/4 Hoagland's no. 2 medium, pH 3.0) were autoclaved, five *M. malabathricum* seedlings

grown for 4 weeks on another vermiculite bed (wetted with the same N-free 1/4 Hoagland's no. 2 medium with pH 5.5) were briefly rinsed with 70% ethanol, then washed with sterile water, then transplanted. The seedlings were inoculated with, *S. rosa* (approximately 1 x 10<sup>5</sup> cells), *B. cepacia* (1 x 10<sup>5</sup> cells), *S. rosa* plus *B. cepacia* (both 1 x 10<sup>5</sup> cells) and a control (sterile water). Bacteria grown on an agar plate of modified Winogradsky's medium (containing 0.5% mannitol and 0.005% yeast extract) were scraped with a loop, suspended in 5 ml sterile water and used as inoculants. The seedlings (*S. rosa*-inoculated, *B. cepacia*-inoculated, *S. rosa* plus *B. cepacia*-inoculated and the control) were grown under the same conditions for 8 weeks to see the effects of the bacterial inoculation on seedling growth under N-deficient conditions.

#### Recovery of rhizoplane microorganisms from *M. malabathricum* seedlings used for inoculation assay

The 8-week-grown seedlings harvested were carefully removed vermiculites from the roots under aseptic conditions, and put them on a plain agar plate to adhere to the gel surface. After 1 day-incubation on the plate, the plants were removed. The resulting agar plate was further incubated at 25°C for 7 days. Mucilaginous, bacterial colony-like small plaques on the plate emerged after the incubation were then spread over MW agar and PD agar plates. Microorganisms grown on these plates were routinely isolated and characterized by determining 16S rRNA gene for prokaryotes and ITS-18S rRNA region for eukaryotes using ITS1 and ITS4 primers (Gardes & Bruns, 1993).

## RESULTS AND DISCUSSION

#### Bacterial Isolates and Their Physiological Properties

We initially investigated microorganisms that comprise the rhizoplane microflora, particularly targeting nitrogen-fixing bacteria. Hence, N-free soft gel medium was used for trapping and observation of the root-associating nitrogen-fixing bacteria. This method was first developed by the Brazilian microbiologist Dobereiner and her coworkers in 1980 (Dobereiner, 1995), but we replaced the 0.2% agarose gel matrix with 0.3% gellan gum. As shown in Fig. 1, gellan gum was highly transparent, so even thin or highly transparent colonies are visible through the glass tube (Hashidoko *et al.*, 2002).

Two rhizoplane bacteria (strains EC-K013 and EC-K014) were isolated from a specimen of *M. malabathricum* grown along an edge of an acid-sulfate

**Fig. 1. Transparency of gellan gum in comparison with agarose**

Winogradsky's mineral solution (pH 6.0) was solidified with gellan gum or highly pure agarose in 1 cm-thick polystyrene cuvettes. Optimal density at 660 nm and 730 nm were measured in triplication at a gel concentration and averaged. Each gel matrix was set at three different concentrations.

paddock at Serapatbaru, Southern Kalimantan. Our physiological and 16S rRNA gene determinations led to the identification of *Sphingomonas rosa* (accession no. AB121233) and *Burkholderia cepacia* (AB121232) for EC-K013 and EC-K014, respectively. The former was non-motile and highly aggregative, while the latter was highly motile and produced mucilaginous materials around the cells. Another *Sphingomonas* sp. was also isolated as the major rhizoplane bacterium of a *M. malabathricum* growing on acid-sulfate clay soil in Paduran, Central Kalimantan. A specimen of *M. malabathricum* grown on peat land at Kalampangan, Central Kalimantan, possessed two *Burkholderia* species, and one of which was tentatively identified as *B. braziliensis*.

#### Effect of rhizoplane bacteria inoculation on the growth of *M. malabathricum* seedlings under acidic, N-free conditions

The screening of rhizoplane epiphytes from a specimen of *M. malabathricum*, grown along the ridge of an acid-sulfate paddock in South Kalimantan, led to the isolation of two heterotrophic bacteria. By use of physiological properties and 16S rRNA gene determination, the two isolates were identified as *S. rosa* and *B. cepacia*, both of which are known to be root-associated bacteria (Takeuchi *et al.*, 1995; Poole *et al.*, 2001). In a 0.3% gellan gum medium, *S. rosa* was non-motile and aggregative, while *B. cepacia* was highly motile.

The test seedlings inoculated with *S. rosa* EC-K013 showed a significantly better growth performance than the control seedlings (Fig. 2). In fact, the seedlings in the control dish showed severe stunting and yellowing, a symptom obviously due to nitrogen-deficiency. In contrast, neither the single-inoculation of *B. cepacia* nor the double-inoculation of *S. rosa* plus *B. cepacia* showed any positive effect on the seedling growth. This meant that nitrogen-fixation is affected by the combination of bacterial species that compose the rhizospheric microflora.

**Fig. 2. Growth stimulating effect of *Sphingomonas rosa* R-1 strain after inoculation on *Melastoma* seedlings grown on N-free medium/vermiculite bed.**

The survival frequency of the inocula was also investigated. As shown in Table 1, both *S. rosa* and *B. cepacia* survived around the rhizosphere and/or rhizoplane; however, their effects on the growth of the seedlings were distinguishable. The growth stimulating properties of *S. rosa* were completely inhibited in the double inoculation of both *S. rosa* and *B. cepacia*. A specimen of improved rice IR 64 with minimal harvests

**Table 1. Survival and effectiveness of the inoculates around the roots of *Melastoma* seedlings grown in N-free 1/4 Hoagland No. 2 medium.**

Treatment	Inoculated bacterium	Effectiveness	
		Aerial	Root
<i>S. rosa</i> inoculated ( $10^5$ cells)	Survived	+++	+++
<i>B. cepacia</i> inoculated ( $10^5$ cells)	Survived	—	+
<i>S. rosa</i> + <i>B. cepacia</i> inoculated ( $10^5$ cells + $10^5$ cells)	Both survived	—	+
Control (sterilized water)	None*		

\* None grew in N-free Winogradsky's media, but certain fungus and saprophytic bacterium were apparent in potato-dextrose agar.

for 4 years in an acidic paddock in Paduran, Central Kalimantan possessed *Burkholderia* sp. on the rhizoplane but no *Sphingomonas* sp. This preliminary observation and our experiment using *M. malabathricum* seedlings described here suggested that these bacterial species occupy different ecological positions in the rhizospheric microflora.

In *M. malabathricum* seedlings inoculated with *S. rosa* EC-K013, a fungal development was uniquely observed in rhizosphere of the harvested seedlings (Table 2). This saprophytic fungus that grow well on PD agar plate was tentatively identified as *Nectria* sp. by sequence determination of ITS-18S rRNA gene region. When *S. rosa* EC-K013 and the accompanying fungus were inoculated together to the N-free soft gel medium, their mix-culture uniquely accelerated growth of nitrogen-fixation of non-nodulation, free-living *Mesorhizobium* sp. that is slow-growing diazotrophic bacterium. This *Mesorhizobium* sp. uniquely grew and spread horizontally

only at appropriate depth of the medium, alike many of micro-aerobic diazotrophs (Fig. 3). Synergistic effect of this rhizo-biocomplex (Hashidoko & Tahara, 2005) is most likely to function in rhizosphere of the *M. malabathricum* seedlings for effective nitrogen fixation.

When the seedlings grown in vermiculite beds wetted with P-free 1/4 Hoagland's No. 2 (pH 5.5) and  $AlPO_4$  powders previously washed with pure water to remove soluble phosphates were preliminarily examined, only the seedlings in the *B. cepacia*-inoculated rhizoplane dish showed better growth. This preliminary result also suggested a capability of *B. cepacia* to solubilize aluminum phosphate powders in acidic soil.

Our laboratory experiments showed that sulfate acid-tolerable *M. malabathricum* possesses functional rhizoplane microflora on its rhizosphere to cope with nutrient deficiencies under strongly acidic conditions. The rhizospheric microorganisms may affect on rhizosphere conditions and bring benefits to the host plant. As known in flavonoids that play a role in rhizobia-symbiosis as signal compounds of leguminous plants, some non-leguminous plants have a strategy of regulating their rhizoplane microorganisms to deliver their maximal capacity by root exudates (Strong & Phillips, 2001). In *M. malabathricum* also, phenolic components in the root exudates stimulated the growth and/or cell aggregation of *S. rosa* in the gellan gum medium (data not shown). Such chemical signals exuded from the rhizosphere are likely to be involved in cross-talk signals among the microorganisms that compose the rhizoplane biocomplex in order to maintain host-beneficial rhizosphere environments.

**Table 2. Rhizoplane microflora of the treated *Melastoma* seedlings grown in N-free 1/4 Hoagland No. 2 medium**

Treatment (after 2-month)	frequency			
	<i>S. rosa</i>	<i>B. cepacia</i>	saprophytic bacterium	Fungi
Inoculation of <i>S. rosa</i>	10/10	0/10	0/10	10/10
Inoculation of <i>B. cepacia</i>	0/10	10/10	0/10	1/10
Inoculation of <i>S. rosa</i> + <i>B. cepacia</i>	4/7	7/7	0/7	0/7
Control (sterilized water)	0/9	2/9*	9/9*	6/9

Rhizomicrofloral investigation was done with 7-10 replications. \**B. cepacia* may be a seed-born bacterium, same as other spontaneous microorganisms. \*\*No growth in MW agar plate was apparent, but it emerged in potato-dextrose medium.

**Fig. 3. Emergence of *Mesorhizobium* sp. in soft gel medium mix-cultured *S. rosa* EC-K013 and *Nectria* sp.**

This horizontal colony emergence was observed only when two inoculants were mix-cultured in N-free soft gel medium. This is most likely a tripartite relationships among these three microorganisms.
