I. Introduction

The cross-coupling reaction now accessible via a variety of organometallic reagents may provide a fundamentally common synthetic methodology (eq 1).

\[ \text{R-M} + \text{R'-X} \xrightarrow{\text{Pd-catalyst}} \text{R-R'} \]  

In 1972, Kumada and Tamao and Corriu reported independently that the reaction of organomagnesium reagents with alkenyl or aryl halides could be markedly catalyzed by Ni(II) complex. Kochi found the efficiency of Fe(III) catalyst for the cross-coupling of Grignard reagents with 1-halo-1-alkenes and Li$_2$CuCl$_4$ catalyst for haloalkanes. The palladium-catalyzed reaction of Grignard reagents was first reported by Murahashi, the synthetic utility of which was then amply demonstrated by Negishi on the reactions of organoaluminum, zinc, and zirconium reagents. After those discoveries, many other organometallic reagents have proven to be highly useful as nucleophiles for the cross-coupling reaction, e.g., organolithiums by Murahashi, organostannans by Migita and Stille, 1-alkenylcopper(I) by Normant, organosilicon compounds by Hiyama. These reac-

† Present address: Kurashiki University of Science and the Arts, Kurashiki 712, Japan.
Organoboron compounds are highly electrophilic, but the organic groups on boron are weakly nucleophilic, thus limiting the use of organoboron reagents for the ionic reactions. The coordination of a negatively charged base to the boron atom has been recognized to be an efficient method of increasing its nucleophilicity to transfer the organic group on boron to the adjacent positive center (1,2-migration reaction). However, intermolecular transfer reaction such as the Grignard-like reaction are relatively rare. Fortunately, organoboron compounds, even organoboronic acids and esters, have sufficiently enough reactivity for the transmetalation to other metals. Transmetalations to silver(I),11 magnesium(II),14 zinc(II),15 aluminum(II),16 tin(IV),17 copper(I),18 and mercury(II)19 halides have been extensively studied. In 1978, Negishi reported that iodobenzene selectively couples with the 1-alkynyl group on lithium 1-hexynyltrialkylborate through a palladium-catalyzed addition–elimination sequence (Heck-type process),20 however, the cross-coupling reaction of organoboron compounds, which involves the transmetalation to palladium(II) halides as a key step, was found to proceed smoothly when these were activated with suitable bases and have proven to be a quite general technique for a wide range of selective carbon–carbon bond formation. Many organometallic reagents undergo similar cross-coupling reactions, but much attention has recently been focused on the use of organoboronic acids in laboratories and industries since they are convenient reagents, which are generally thermally stable and inert to water and oxygen, thus allow their handling without special precautions. This review summarizes the palladium-catalyzed cross-coupling reaction of organoboron compounds with organic halides or triflates, the reaction mechanism, the scope of synthetic applications, and other related catalytic processes with transition-metal complexes are discussed.

II. Synthesis of Organoboron Reagents

A. Synthesis from Organolithium or Magnesium Reagents

The classical synthesis of aryl- and 1-alkenylboronic acids or their esters from Grignard reagents or lithium reagents and trialkyl borates is an efficient method for making relatively simple boron compounds in large quantities (eqs 2 and 3). The first stereocontrolled synthesis of arylboronic acids and esters involves the reaction of a (Z)- or (E)-2-buten-2-ylmagnesium bromide with trimethyl borate (eq 4).

However, the application of these classical procedures for organoboronic acid or ester synthesis may suffer from the contamination of small mount of the opposite stereoisomers, or bis-alkylation leading to the borinic acid derivatives and the formation of trialkylboranes. A recent useful variant utilizes organolithium reagents and triisopropyl borate, followed by acidification with HCl to give directly alkyl-, aryl-, 1-alkynyl-, and 1-alkenylboronic esters in high yields, often over 90% (eq 5). Trisopropyl borate is shown to be the best of available alkyl borates to avoid such multiple alkylation of the borates.

Very recently, arylboronic esters have been directly obtained from aryl halides via the cross-coupling reaction of (alkoxy)boron (eq 6). The reaction tolerates various functional groups such as ester, nitrile, nitro, and acyl groups.

B. Hydroboration of Alkenes and Alkynes

The addition of dialkylboranes such as 9-borabicyclo[3.3.1]nonane (9-BBN), disiamylborane, or dicyclopentadienylborane to 1-alkenes gives mixed alkylboron compounds. The reaction is essentially quantitative, proceeds through cis anti-Markovnikov addition from the less hindered side of double bond, and can tolerate various functional groups. The 9-alkyl-9-BBN derivatives thus obtained are particularly useful for the transfer of primary alkyl groups by the palladium-catalyzed cross-coupling reaction since the 9-alkyl group exclusively participates in a catalytic reaction cycle (eq 7).

The use of the hydroboration reaction is especially valuable for the synthesis of stereodefined or functionalized alkenylboronic acids and their esters. The general and most convenient method is the hydroboration of a terminal alkylene with catecholborane (2a) to produce 1-alkenylboronic ester (eq 8). The hydroboration with 2a can also be carried out under milder conditions by using palladium, rhodium, or nickel catalysts. The hydroboration of alkynes with dihaloarabanes (HBCl₂,SMe₂ or HBB₁₂,SMe₂) followed by hydrolysis to vinylboronic acids or alcohols gives stereocontrolled synthesis of alkenylboronic acids and their esters (3b) have been used for the same purpose. However, a recent and more convenient variant is the in situ preparation of HBCl₂ in a hydrocarbon solvent from BCl₃ and HSiEt₃. The reagent exhibits extremely high reactivity to alkenes and alkynes allowing the hydroboration to proceed at −78 °C. Disiamylborane (2c) is also one of the mildest and selective hydroboration reagents for...
functionalized alkynes, but their use for the cross-coupling can be more difficult than that of boronic acids or their esters. Hydroboronation of terminal alkynes with 9-BBN leads to the formation of significant quantities of dihydroboration products. However, dihydroboration of 1-alkynes, followed by deboration with benzaldehyde provides $\text{g-[(E)-l-alkenyll-9-BBN derivatives}}$ (3d) in high yields with high trans selectivity.  

These reactions work well with terminal and symmetrical internal alkynes, but the difficulties are often encountered by the lack of regiochemistry or chemoselectivity (e.g., reduction of functional groups) upon addition to general internal alkynes or functionalized alkynes. Diisopinocampheylborane has been used as a reagent for asymmetric hydroboration, and additionally it has attractive features as a hydroboration reagent for alkynes, e.g., the inertness to many functional groups except aldehyde and ketone carbonyls, the high regioselectivity resulting from its bulkiness, and ease of dealkylation to boronic esters under neutral conditions. The hydroboration of propargyl chloride and ethyl propiolate provides terminal boron derivatives with excellent regiochemistry, whereas the hydroboration with catecholborane or disiamylborane (2c) gives an inseparable mixture of internal and terminal boron adducts (eq 9).

Terminal and internal (Z)-1-alkenylboronates are prepared from (Z)-(haloalkenyl)boronic esters (4) which can be readily obtained by hydroboration of 1-halo-1-alkyne (eq 10). The internal $\text{S}_2$ reaction with KHB(OPr$_3$)$_2$ or organolithiums takes place with complete inversion of configuration at the sp$^2$ carbon (eqs 11 and 12). The reaction is almost quantitative and highly selective (inversion $>$ 99%). Thus, the boron derivatives prepared in situ can be directly used for the following cross-coupling reaction without further purification. On the other hand, alklylation of 4b with organozinc reagents in the presence of a palladium catalyst stereospecifically provides (E)-1-alkenylboronates (7) which are not available by conventional hydroboration of internal alkynes (eq 13).

C. Haloboration of Terminal Alkynes

Terminal 2,2-diorgano-1-alkenylboronates (9) are made by bromoboration of a terminal alkyne to $\beta$-bromo-1-alkenylboronic ester (8) (eq 14) followed by the palladium-catalyzed displacement of the $\beta$-halogen with organozinc reagents which proceeds strictly with retention of configuration (eq 15). Haloboranes add to terminal alkynes via a cis anti-Markovnikov manner; however, the bromoboration of acetylene itself exceptionally provides a trans-adduct which gives the corresponding (E)-1-alkenylboronates (10) by the reaction with organozinc halides (eq 16). The addition of tribromoborane to acetylene first gives a cis-adduct, which then isomerizes to the trans-isomer during its isolation. These two-step procedures are useful to achieve a formal carboboration of alkynes with a variety of organic groups.

D. Miscellaneous Methods

An efficient route to (E)-1-alkenylboronates from carbonyl compounds is achieved by the reaction with lithio(borv1)methanes. The (E)/(Z) isomeric ratio is
Chemical Reviews, 1995, Vol. 95, No. 7

reported to be ~20:1 (eq 17). On the other hand, a trimethylsilyl analog gives a cis-rich isomer (~70:30) on reaction with aldehydes (eq 18). The reaction of lithiotriborylmethane with aldehydes or ketones yields 1,1-alkenyldiborates (eq 19).

Miyaura and Suzuki esters of boronic acids are reported to be isolated by flash chromatography on silica gel.

III. Palladium-Catalyzed Reactions of Organoboron Compounds and Their Mechanism

A. Cross-Coupling Reaction

A general catalytic cycle for the cross-coupling reaction of organometallics, which involves oxidative addition-transmetalation-reductive elimination sequences, is depicted in Figure 1. Although each step involves further knotty processes including ligand exchanges, there is no doubt about the presence of those intermediates (11 and 12) which have been characterized by isolation or spectroscopic analyses. It is significant that the great majority of cross-coupling reactions catalyzed by Ni(0), Pd(0), and Fe(I) are rationalized in terms of this common catalytic cycle.

Oxidative addition of 1-alkenyl, 1-alkynyl, allyl, benzy1, and aryl halides to a palladium(0) complex affords a stable trans-a-palladium(II) complex (11). The reaction proceeds with complete retention of configuration for alkyl halides and with inversion for allylic and benzylic halides. Alkyl halides having β-hydrogen are rarely useful because the oxidative addition step is very slow and may compete with β-hydride elimination from the a-organopalladium(II) species. However, it has been recently shown that iodoalkanes undergo the cross-coupling reaction with organoboron compounds (sections IV.F and VI).

Oxidative addition is often the rate-determining step in a catalytic cycle. The relative reactivity decreases in the order of I > OTf > Br >> Cl. Aryl and 1-alkenyl halides activated by the proximity of electron-withdrawing groups are more reactive to the oxidative addition than those with donating groups, thus allowing the use of chlorides such as 3-chloroenone for the cross-coupling reaction.

A very wide range of palladium(0) catalysts or precursors can be used for cross-coupling reaction. Pd(PPh3)4 is most commonly used, but PdCl2(PPh3)2 and Pd(OAc)2 plus PPh3 or other phosphine ligands are also efficient since they are stable to air and readily reduced to the active Pd(0) complexes with organometallics or phosphines used for the cross-coupling. Palladium complexes that contain fewer than four phosphine ligands or bulky phosphines such as tris(2,4,6-tri-
methoxyphenyl)phosphine are, in general, highly reactive for the oxidative addition because of the ready formation of coordinate unsaturated palladium species.55

Reductive elimination of organic partners from 12 reproduces the palladium(0) complex.56–58 The reaction takes place directly from cis-12, and the trans-12 reacts after its isomerization to the corresponding cis-complex (eqs 24 and 25). The order of reactivity is diaryl- > (alkyl)aryl- > dipropyl- > diethyl- > dimethylpalladium(II), suggesting participation by the π-orbital of aryl group during the bond formation (eq 24).58b Although the step of 1-alkenyl- or 1-alkenyln palladium(II) complexes is not studied, the similar reactive for the oxidative addition because of the is inhibited by excess phosphine which is an intermediate on the alkyl-alkyl coupling, related platinum(II) complexes.59

The thermolysis of cis-(dialkyl)palladium(II)-L₂, which is an intermediate on the alkyl-alkyl coupling, is inhibited by excess phosphine (L), hence it is considered to be initiated by the rate-determining dissociation of phosphine ligand (L) producing a three-coordinated cis-(dialkyl)palladium(II)-L complex (dissociative mechanism, eq 25).67 Thus, the effect of phosphine ligands is comparable to the order of ease of their dissociation: dppe ≪ PEt₃ < PET₃Ph < PMePh₂ < PEtPh₂ < PPh₃.

On the other hand, cis-alkenyl- and cis-arylpalladium(II) complexes, which are intermediates in most of cross-coupling reactions discussed here, directly eliminate organic partners from the four-coordinated complex (nondissociative—nonassociative mechanism, eq 24).58

Although the mechanism of oxidative addition and reductive elimination sequences are reasonably well understood and are presumably fundamentally common processes for all cross-coupling reactions of organometallics, less is known about the transmetalation step because the mechanism is highly dependent on organometallics or reaction conditions used for the couplings.

The transmetalation between 1-hexenylboronic acid and palladium(II) acetate was first reported by Heck.60 The in situ preparation of (E)- or (Z)-1-alkenyln palladium(II) species and its addition to ethyl acrylate readily proceeds at room temperature while retaining their original configurations (eq 26).58 Before this observation, Davidson and Triggs reported the dimerization of phenylboronic acid with Na₂PdCl₄ catalyst (eq 27),61 although it still remains obscure whether the reaction indeed proceeds through the transmetalation or other processes.

\[
\text{BuCH}=\text{CH} \text{(OH)}_{2} + \text{Pd(OAc)}_{2} + \text{CH}_{2} = \text{CHCO}_{2} \text{Et} \rightarrow \text{BuCH}=\text{CHCH}=\text{CHCO}_{2} \text{Et} \quad (26)
\]

\[
2 \text{Pb}=\text{OH}_{2} + \text{NaPdCl}_{4} \rightarrow \text{Ph-Ph} \quad (27)
\]

In spite of these previous reports, organoboron compounds are quite unlikely to participate in the catalytic cycle of cross-coupling reaction since they are inert to the organopalladium(II) halides (11) such as PdCl₂, PdCl₂(PPh₃)₂, or PhPd(PPh₃)₂.62 There is some experimental evidence for the transmetalation to the transition metals. The reaction of organoboranes with organomercurials proceeds under neutral conditions when Hg(OAc)₂, Hg(OR)₂, or HgO is used.63 It has also been reported that the addition of sodium hydroxide or other bases exerts a remarkable effect on the transmetalation rate of organoboron reagents with metallic halides, such as mercuric,64 silver,13 auric,64 and platinitic halides.64 Thus, the transmetalation with transition-metal complexes appears to proceed well indeed, but the choice of suitable bases and ligands on transition-metal complexes is essential.

Preliminary successful results have reported that (E)-1-hexenyl-1,3,2-benzodioxaborole couples with iodobenzene in the presence of Pd(PPh₃)₃ and bases to produce a mixture of desired and undesired coupling products depending on the base and the catalyst used (eq 28).65

\[
3a (R''=\text{Bu}) + \text{Ph-I} \rightarrow \text{Ph-Ph} \quad (28)
\]

The formation of normal coupling product 13 predominates when sodium hydroxide or alkoxides are used, whereas a combination of triethylamine and a palladium catalyst without phosphine ligands leads almost exclusively to an abnormal head-to-tail coupling product 14 (Table 1).59b

The formation of the abnormal coupling product 14 can be best understood by the mechanism of Heck reaction66 for vinylic metal compounds, that often predominates on the cross-coupling reaction of weakly

nucleophilic organometallics, such as 1-alkenylmercury,
-iodides,68 and -tin compounds.69

Organopalladium(II) halides add mainly to the
electron-deficient carbon of unsymmetrical alkenes66
to give 15, which readily isomerizes to 16 via a
sequence of elimination and readdition of the hydri-
dopalladium(II) iodide. Finally, the elimination of
iodoborane with the aid of triethylamine gives the
head-to-tail cross-coupling product. A
deuterium-labeling study proves the addition-elimination mech-
anism where a P-hydrogen transfers to the terminal
carbon (Figure 2).70

The cross-coupling reaction of organoboron com-
ponents with organic halides or triflates selectively
reacts in the presence of a negatively charged base,
such as sodium or potassium carbonate, phosphate,
hydroxide, and alkoxide.70,78 The bases can be used
as aqueous solution, or as suspension in dioxane or
DMF. In contrast, the cross-coupling reaction with
certain electrophiles, such as allylic acetates,65b 1,3-
butadiene monoxide,71 and propargyl carbonate,72
occurs under neutral conditions without any as-
sistance of base. The transmetalation of organoboron
components with palladium halides under basic or
neutral conditions can be considered to involve the
following three processes: eqs 29, 32, and 39.

An alternative transmetalation process found dur-
ing our investigations is that organoboron compounds
readily transfer their organic groups to (alkoxo)-
palladium(II) complexes under neutral conditions (eq 32).

Although the cross-coupling reaction with organic
halides generally requires the assistance of bases,
allylic phenoxides and cinnamyl acetate react with
1-alkenylborates under neutral conditions to yield the

During such a transmetalation, it is conceivable
that the coordination of palladium(II) species to the
carbon–carbon multiple bond constitutes the initial
step for the interaction of both species and probably
this interaction serves to accelerate the ligand
exchanges.74 Thus, the alkoxyl group exclusively
reacts with iodobenzene, but it is surprising that
the transfer of primary alkyl group occurs quite
smoothly compared with 1-alkenyl or phenyl groups.

Thus, the quaternization of trialkylboranes ac-
celerates indeed the transmetalation to the pallad-
ium(II) halides. Although there is no direct evidence
that the boronate anions, such as RB(OH)3−, are
capable of effecting the transmetalation, it is
quite reasonable to assume the similar effect of base
for the transmetalation of organoboronic acids. The
cross-coupling reaction of arylboronic acids with aryl
halides at pH = 7–8.5 is retarded relative to the
reaction at pH = 9.5–11.75 The pKa of phenylboronic
acid is 8.8, thus suggesting the formation of the
hydroxyboronate anion [RB(OH)3−] at pH > pKa and
its transmetalation to the palladium(II) halides. The
formation of ArB(OH)3− at pH = 11–12 has been
recently reported.76

Recently, fluoride salts have been found to effect
the cross-coupling reactions of 1-alkenyl- and
arylboron compounds (eq 31).77 The species that under-
goes transmetalation is assumed to be organo(tri-
fluoromethyl)borate ion.

An alternative transmetalation process found dur-
ing our investigations is that organoboron compounds
readily transfer their organic groups to (alkoxo)-
palladium(II) complexes under neutral conditions (eq 32).
allylacetoxy)palladium(II) intermediates generated by oxidative addition may undergo transmetalation without bases. reaction intermediates\(^{85}\) or isolated\(^{78,80}\) from the reaction of organopalladium(II) halides with sodium hydroxide or methoxide. It is not yet obvious in many reactions which process shown in eq 29 or 39 is predominant; however, the formation of alkoxo-, hydroxo-, or acetatopalladium(II) intermediate should be considered to be one of the crucial transmetalation processes in the base/palladium-induced cross-coupling reactions.

The reaction of 1-alkenylboronates with haloenones shows a characteristic feature for the (alkoxo)palladium mechanism (eq 40).\(^{66}\) The cross-coupling reaction with haloenones is accelerated by exceptionally weak bases such as NaOAc or even Et\(_3\)N, when methanol is used as a solvent. The results cannot be explained by the ate-complex mechanism shown in eq 27, and can be best understood by the formation of (alkoxo)palladium(II) intermediate (28) since 27 readily exchanges the halogen ligand with methanol due to its strong trans effect of the electron-poor alkenyl group (eq 41).

![Figure 5. Formation of palladium(II) acetate and its transmetalation.](image)

The palladium-catalyzed cross-coupling reaction of (alkoxy)diboron derivatives provides the first one-step procedure for arylboronic esters from aryl halides (eq 6).\(^{87}\) Potassium acetate is one of the best bases to achieve a selective cross-coupling, and stronger bases such as potassium carbonate or phosphate give biaryl byproducts arising from further coupling of the product with aryl halides.

The treatment of the phenylpalladium(I) bromide with KOAc gives a trans-PhPdOAc(PPh\(_3\))\(_2\) (29)\(^{87,88}\) which exhibits high reactivity toward (alkoxy)diboron derivatives selectively giving the phenylboronate at room temperature (Figure 5). Thus, the transmetalation involving formation of 29 and its reaction with the diboron is proposed as a key step. The acetoxy anions do not act as a base to coordinate with boron atom under the given reaction conditions. The catalytic cycle is shown in the Figure 6.

A similar (methoxo)platinum intermediate has been recently reported for the transmetalation between a cationic platinum(II) complex and potassium teraphenylborate (eq 42).\(^{88}\)

![Figure 6. Cross-coupling with (alkoxy)diboron (eq 6).](image)

**B. Other Catalytic Process by Transition-Metal Complexes**

Recently, transition-metal complexes have been reported as efficient catalysts for the addition of metal reagents, including magnesium, aluminum, silicone, zinc, germanium, and tin compounds to alkenes and alkynes.\(^{90}\) Although the related reactions of boron compounds are not yet well developed, the Rh-, Pd-, or Ni-catalyzed hydroboration of alkenes\(^{27}\) and alkynes\(^{27b}\) (eqs 43-46) has been extensively studied since the catalyst allows the reaction under very mild conditions and often can direct the course of the addition of borane to a different selectivity than the uncatalyzed reaction (eq 43).\(^{91m}\) Asymmetric hydroboration of styrene is achieved using a bidentate chiral ligand (eq 44).\(^{91l}\) Hydroboration of 1,3-butadiene stereoselectively affords a (Z)-crotyleboronate with a palladium(0) complex (eq 45).\(^{91k}\) The PdCl\(_2\)(dpfp) and NiCl\(_2\)(dppe) or -(dppp) complexes afford good results for the hydroboration of alkynes (eq 46).\(^{27b}\)

The Pd(0)-catalyzed addition of the B-S bond to terminal alkynes regio- and stereoselectively produces (Z)-2-(organothio)-1-alkenylboron reagents (eq 47).\(^{92}\) The addition of (alkoxy)diboron to alkynes to give cis-bis(boryl)alkenes (diboration) is catalyzed by a platinum(0) catalyst (eq 23). The additions proceed regioselectively in favor of terminal boron adducts to produce (Z)-1-alkenylboron compounds through a trans addition of the X-B bond to 1-alkynes. The mechanism is fundamentally different from the uncatalyzed process and is postulated to proceed through the oxidative addition of the X-B bonds (X= H, RS, Y2B) to the transition-metal complex [M(0)] to form X-M-BY\(_2\) species (32), followed by the migratory cis insertion of alkenes or alkynes into the X-M bond, and finally the reductive
elimination of alkenylboron compounds from 33 regenerates the M(0) complex, as shown in Figure 7.27c,47,92

The oxidative adducts such as B–Rh–H and B–Ir–H intermediates27d in the catalytic hydroboration, and the B–Pt–B intermediate27g in the diboration have been isolated and fully characterized by X-ray analyses, and by observing its insertion reaction to alkynes. Since the catalytic cycle is a very powerful and fundamentally common process with a group 10 transition metal, the further uses of this type of reaction will certainly be exploited in the future.

The oxidative addition of the C–Hg bond to Pd(0) complex is involved in the catalytic carbonylation and the homo coupling of aryl- or vinylmercurials.94 Similar reaction type such as dimerization,95 protolysis of the C–B bonds (eq 48),96 and Heck-type addition (eq 49)97 of aryl- or alkenylboronic acids take place in moderate yields. The reactions can be catalyzed by palladium(0) catalysts without phosphine ligands. The mechanism has not yet been elucidated in detail, but it is reasonable to speculate the oxidative addition of the C–B bond to palladium(0) complex.

**Figure 7.** A general catalytic cycle for additions.

The mechanism for the carbonylative cross-coupling reaction for synthesis of ketones is discussed in section VI. The mechanisms for alkoxy carbonylation and dimerization of organoboron compounds, which require a reoxidant of palladium similar to the Wacker process, is discussed in section VII.

**IV. Cross-Coupling Reaction**

### A. Coupling of 1-Alkenylboron Derivatives: Synthesis of Conjugated Dienes

The stereo- and regioselective syntheses of conjugated alkadienes are of great importance in organic chemistry by themselves, as well as their utilization in other reactions such as the Diels–Alder reaction. A number of new methods for the preparation of conjugated dienes and polyenes have been developed by utilizing various organometallic reagents. Among these procedures, the most promising ones are perhaps those based on the direct cross-coupling reaction of stereodefined alkenylmetals with stereodefined haloalkenes in the presence of a catalytic amount of a transition-metal complex.5,8,10 Although the representative 1-alkenylmetal reagents undergo a similar type of coupling reactions with haloalkenes, there are several limitations when one wishes to obtain unsymmetrical dienes without homocoupling, highly functionalized dienes, or stoichiometric conditions relative to metal reagents and halides. Thus, much attention has been recently been focused on the use of 1-alkenylboronic acids or their esters,20 because a variety of 1-alkenylboron derivatives are now readily available, as discussed in the section II.

The first observation to prepare conjugated dienes is shown in eq 50.65,98–100 The high yield of diene is obtained when relatively strong bases such as sodium ethoxide and hydroxide are used together with a phosphine-based Pd complex, e.g., Pd(PPh₃)₄ and PdCl₂(PPh₃)₂. In general, a combination of Pd(PPh₃)₄ and sodium ethoxide works satisfactorily for the coupling with 1-bromo-1-alkenes, and PdCl₂(PPh₃)₂ and aqueous sodium hydroxide for 1-iodo-1-alkenes. The use of palladium catalyst without phosphine ligand or weak bases (KOAc or Et₃N) has a tendency to be contaminated by undesired head-to-tail coupling product (36).70 The reaction can be carried out in aqueous media by using water-soluble phosphine palladium catalyst.101
Although disiamyl- or dicyclohexylborane is a selective and efficient hydroboration reagent of alkynes, 1-alkenyl dialkyl boranes thus obtained give relatively poor yields of coupling products (~50%) with low stereoselectivity. The difficulty appears to be due to side reactions arising from the protodeboronation with water or alcohols and the transfer of secondary alkyl group to the palladium(II) halide. Some loss of the reagent decreases the yields of coupling products and the transfer of secondary alkyl group forms an undesirable palladium(II) hydride species which induces isomerization of the double bond. The protodeboronation of 1-alkenylboron compounds with alcohols is faster than with water, and it decreases in the following order: 9-BBN > B(cyclohexyl)2 > B(Sia)2 > B(OR)2. Thus, the high yields and high isomer purity exceeding 99% can be achieved by using 1-alkenyl boronic acids or their esters. Yields and stereoselectivity on the cross-coupling of (Z)-1-hexenylboron reagents with iodo-benzene are shown in Table 3.99

Thus, the oxidation of the two boron-sp^3 carbon bonds with triethylamine N-oxide prior to the coupling solves the difficulty arising from the B-C bond protonolysis and the contamination of the coupling product with alkyl group (eq 51).104,105

\end{align*}
\]

The absence of a convenient route to 9-vinyl-9-BBN has severely limited the use of 9-BBN derivatives in this coupling. However, the reagents are now available under very mild conditions by a sequence of dihydroboration of terminal alkynes and dehydroborylation with an aromatic aldehyde. The cross-coupling with organic halides readily undergoes in the refluxing THF in the presence of Pd(PPh3)4 and an aqueous NaOH (eq 52).30,106

Bombykol is a well-known pheromone, first isolated from Bombyx mori L. Bombykol and the related three isomers were synthesized by the cross-coupling reaction. Three alkenylboronates or boronic acids (37–39) and two vinlylic halides (40 and 41) required for the coupling are prepared by starting from two alkynes. The stereoselective syntheses of (E)- and (Z)-1-alkenylboronic acids or esters are discussed in the previous section (eqs 8 and 11). Halogenation of the corresponding alkenylboronic acids with iodine or bromine provides (E)- and (Z)-haloalkenes from the same starting material (eqs 56 and 57).107 The palladium and base-assisted coupling of each five and eleven units stereoselectively provides bombykol and its three geometrical isomers (eqs 58–61).108

(Z,E)- or (E,Z)-dienic structures are rather common in the sex pheromones of insects. The procedure has been successfully applied to the syntheses of European grape wine moth,109,110 red bollworm moth,109 and Egyptian cotton leafworm109,111 sex pheromones.

Since a variety of 1-alkenylboron reagents including (E)- and (Z)-isomers are now available, their cross-coupling with 1-halo-1-alkenes affords various stereodefined alkadienes and trienes.88–100 Many syntheses of alkadienes and trienes such as unsaturated fatty acid amides,112 alkenylsilanes,106,113...

diffluoroalkenes,¹⁰⁴,¹¹³ cyclic alkenes,¹¹⁴ (C10)-allofarnesene,¹¹⁵ trisporol B,¹¹⁶ and vinylsulfides¹¹⁸ are reported by application of Pd-catalyzed cross-coupling. The representative syntheses and reaction conditions are summarized in Table 4.

The coupling rate enhancement was realized by Kishi by using an aqueous TlOH in place of sodium or potassium alkoxide or hydroxide. The cross-coupling between (E)-1-alkenylboronic acid and (Z)-iodoalkene stereoselectively furnished the C75-C76 bond formation of palytoxin at room temperature (Figure 8).¹¹⁹

Roush, Nicolaou, and Evans have also demonstrated the efficiency of thallium hydroxide on the synthesis of an aglycone of antibiotic kijanimicin,¹²⁰ chlorothricolide,¹²¹ (5Z,8Z,10E,12R,14Z)-12-hydroxy-5,8,10,14-icosatetraenoic acid [(12R)-HETE],¹²² and a macroline antibiotic rutamycin B¹²³ (Figure 9). This modification of base has been realized on the assumption that the transmetalation involves a palladium(II) alkoxide or hydroxide intermediate (20 in eq 39); namely, thallium base may accelerate the formation of 20 by forming water-insoluble thallium salts instead of NaX. However, another process, i.e., the transmetalation of alkenylboronic acids to thallium salts giving an alkenylthallium(I) or -(III) species, has not yet been investigated.¹²⁴

Hydroboration of enynes provides 1,3-alkadienylboron derivatives. The coupling of dienylboron compounds with haloalkenes allows a short-step synthesis of conjugated trienes; for example, the synthesis of leukotriene B₄ shown in eq 62.¹²⁵,¹²⁶ Due to the
difficulty of purification of a geometrical mixture, the stereodefined syntheses might be essential for such trienes. As discussed previously, the coupling reaction is carried out more efficiently by 1-alkenylboronic acids or esters; however, 1-alkenyl(disiamyl)boranes have been often used as a coupling reagent since hydroboration of alkynes having allylic or propargylic hydroxy functional groups does not afford good results with catecholborane. Aqueous lithium hydroxide is shown to be one of the best bases that avoids the C-B bond breaking during the cross-coupling (eq 62).126

A reverse combination of 1-alkenylboronates and l-halo-1,3-alkadienes is expected to lead to the same trienes, but this combination is generally not recommended because of the synthetic problems of unstable dienyl halides and the side reaction eliminating hydrogen halides with bases to produce the corresponding enyne. However, the thallium base allows this combination for synthesis of the conjugated pentaene (eq 63).127

β-Halo-α,β-unsaturated ketones and esters are highly susceptible to S_N2 displacement at the carbon attached to halogen, thus strong bases are undesirable for such substrates.86,128–131 However, relatively weak bases, such as sodium acetate and even triethylamine, are effective when the reaction is conducted in alcohol solvents (eqs 40 and 64).86 Sodium acetate suspended in methanol, and aqueous or solid carbonate in ethanol give best results for haloenone and halo ester, respectively. PdCl_2(PPh_3)_2 or a combination of Pd(OAc)_2 plus PPh_3 (4 equiv) is desirable to achieve high yields. The cis/trans isomerization is rarely observed in the palladium-catalyzed cross-coupling, but the reaction with (Z)β-bromoacrylate gives a mixture of stereoisomers. PdCl_2(dppe) is effective for carrying out the reaction at room temperature in order to depress the isomerization during the coupling (eq 65).129

Conjugated enynes are of importance in themselves, as well as in their utilization for synthesis of conjugated dienes. The cross-coupling reaction of 1-alkenyl(disiamyl)boranes (3c) with 1-bromo-1-
Reactions of Organoboron Compounds

The cross-coupling reaction of 1-alkenylboronates is useful for alkenylation of haloarenes (eq 67). The reaction proceeds more rapidly in homogeneous conditions (aqueous base in DME), but the reasonable yields are also obtained under heterogeneous conditions. For example, K2-

The cross-coupling reaction of tris(2-ethoxyethylenyl)borane (42) or 2-(2-ethoxy-1-alkenyl)-1,3,2-benzodioxaboroles (43) with iodoarenes produces styryl ethers in high yields in the presence of Pd(PPh3)4 and powdered NaOH suspended in THF. Since 42 and 43 have a tendency to undergo base-induced decomposition on prolonged heating, it is desirable to use iodoarene derivatives as a substrate or an excess boron reagent for relatively unreactive haloarenes. Removal of the MOM protecting group, followed by cyclization gives benzo[b]furans in high yields by treatment with HCl in methanol (presumably to give cyclic acetals first), followed by dealkoxylation with phosphoric acid (PPA) at 100 °C (eq 71).

Conversion of haloarenes to areneethanal precursors also can be carried out by the cross-coupling reaction of (2-organothio-1-alkenyl)boron derivatives which will be discussed in the section IV.E.

B. Coupling of Arylboron Derivatives: Synthesis of Biaryls

The first observed method to prepare biaryl is shown in eq 72. After this discovery, various modifications have been made for the reaction conditions. A combination of Pd(PPh3)4 or PdCl2(PPh3)2 and aqueous Na2CO3 in dimethoxyethane (DME) works satisfactorily in most cases. The reaction proceeds more rapidly in homogeneous conditions (aqueous base in DME), but the reasonable yields are also obtained under heterogeneous conditions. For example, K2-

The combination with other bases such as Et3N, NaHCO3, Cs2CO3, Tl2CO3, and K2PO4 with or without Bu4NCl and 18-crown-6 also have been used. The reaction is successful for aryl triflates and iodo- and bromoarenes. Chlorobenzene derivatives are generally quite inert to oxidative addition, but some of \( \pi \)-deficient heteroaryl chlorides gives coupling products. The reaction proceeds more rapidly in homogeneous conditions (aqueous base in DME), but the reasonable yields are also obtained under heterogeneous conditions. For example, K2-

Cyclodehydration of 2-hydroxy- or 2-aminobenzeneethanal derivatives is known as a general procedure for the synthesis of benzo-fused heteroaromatic compounds. Although numerous modifications of this general method have been studied, the major difficulty seems to be the lack of a general method for the required \( \pi \)-functionalized areneethanal.
CO$_3$ suspended in toluene works well for base-sensitive reactants.$^{149}$ The coupling is also carried out in an aqueous medium by using water-soluble phosphine ligand (m-Na$_3$SC$_6$H$_4$PPh$_2$).$^{101}$ Although the conditions using such bases are not entirely compatible with the functional groups present in the desired reactants, the extremely mild conditions using CsF or Bu$_4$NF (eq 31) allow the synthesis of various functionalized biaryls (eq 73).$^{77}$

\[
\text{Ph-B(OH)$_2$ + Br}^+ \rightarrow \text{Ph-CH$_2$COCH$_3$}
\]

(73)

Phosphine-based palladium catalysts are generally used since they are stable on prolonged heating; however, extremely high coupling reaction rate can sometimes be achieved by using palladium catalysts without a phosphine ligand such as Pd(OAc)$_2$, [(η$^2$-C$_5$H$_5$)PdCl$_2$], and Pd$_2$(dba)$_3$C$_6$H$_6$.$^{75,150}$ Phosphine-free palladiums are approximately 1 order of magnitude more active than ArPd($^2$I)-PPh$_3$, both of which are in turn markedly more active than Pd(PPh$_3$)$_4$ (eq 74).

\[
\text{PhB(OH)$_2$ + I}^- \rightarrow \text{Ph-NO$_2$}
\]

(74)

catalyst: Pd(PPh$_3$)$_4$ (8 h, 23%); PhPd[PPh$_3$]$_2$(0.33 h, 53%); Pd(OAc)$_2$(0.75 h, 98%)

Although steric hindrance of aryl halides not a major factor for the formation of substituted biaryls, low yields are resulted in when using ortho-disubstituted arylboronic acids. For example, the reaction with mesitylboronic acid proceeds only slowly because of steric hindrance during the transmetalation to palladium(II) halide. The addition of strong bases, e.g., aqueous NaOH or Ba(OH)$_2$, both in benzene and DME exerts a remarkable effect on the acceleration of the coupling rate (eq 75).$^{151-153}$ Although weak bases give better results for less hindered arylboronic acids, the order of reactivity for mesitylboronic acids corresponds to the basic strength: Ba(OH)$_2$ > NaOH > K$_2$PO$_4$ > Na$_2$CO$_3$ > NaHCO$_3$.$^{151}$

\[
\text{MeO} - \text{B(OH)$_2$ + Br}^+ \rightarrow \text{MeO} - \text{Ar}
\]

(77)

Ar = Ph 54% 27%
Ar = o-MeOC$_6$H$_4$ 79% 3%

The cross-coupling reaction of arylboronic acids is largely unaffected by the presence of water, tolerating a broad range of functionality, and yielding nontoxic byproducts. The reaction offers an additional great advantage of being insensitive to the presence of ortho-functional groups or heteroaromatic rings. Gronowitz has shown that unsymmetrically substituted bithienyls$^{141,158}$ and thienylpyridines$^{159}$ can be regioselectively synthesized by the cross-coupling reaction of thienylboronic acids (eq 78). Arylation of 5-bromonicotinates is demonstrated by Thompson$^{160}$ (eq 79). Diethyl(3-pyridyl)borane synthesized by Terasi$^{147}$ is a unique air-stable reagent for the heteroarylation (eq 80).
Reactions of Organoboron Compounds

The ready availability of ortho-functionalized arylboronic acids by directed ortho-metalation—boronation sequence provides a synthetic link to the cross-coupling protocol. Snieckus has amply demonstrated that the sequence has considerable scope for the synthesis of unsymmetrical biaryls, heterobiaryls, and terphenyls.161 (eq 81). The utility of the sequence has recently shown by the industrial-scale synthesis of a nonpeptide angiotensin II receptor antagonist.162 (eq 82).

As a consequence, the reaction has been used extensively in the synthesis of natural and unnatural products and pharmaceuticals such as saddle-shaped host compounds,163 ferrocene derivatives,164 bis-cyclometalating N-C-N hexadentated ligands,165 helically chiral ligands,166 michellamine,167 biphenoxy-mycine A,167 vancomycin,168 receptor molecules for oxo acids,169 leukotriene B4 receptor antagonist,170 hemispherand,171 1,1'-bi-2-naphthol,161 facsalpylin and streptonigrin alkaloids,172 ungerimine and hippadine alkaloids,161i and other biarils.173 Some of examples are summarized in Figure 10.

Aromatic, rigid-rod polymers play an important role in a number of diverse technologies including high-performance engineering materials, conducting polymers, and nonlinear optical materials. The cross-coupling reaction of arylboronic acids and dihaloarenes for the synthesis of poly(p-phenylene) was first reported by Schlüter.174 The method has been extensively applied to monodisperse aromatic dendrimers,175 water-soluble poly(p-phenylene),176 planar poly(p-phenylene) fixed with the ketoimine bonds,177 poly(p-phenylene) fused with polycyclic aromatics,178 and nonlinear optical materials179 (Figure 11).

Arylboronic acids are also efficient reagents for arylation of 1-alkenyl halides and triflates. Arylation of various haloalkenes such as α,α,β-unsaturated lactams,180-182 6-[(alkoxyacarbonyl)aminol]-1-bromocyclohexene,181 1-iodo-3,4,6-tri-O-(triisopropylsilyl)-D-glucal182 (eq 83), and the bromokalene precursor for (Z)-tamoxifen synthesis183 are achieved by the cross-coupling reaction of arylboronic acids. Arylcycloalkenones are prepared by the cross-coupling with corresponding triflates184 (eq 84). For the arylation of triflates, higher yields can be obtained in the presence of LiCl or LiBr (see: section IV.D).

Figure 10. Synthesis of biaryls.

Figure 11. Aromatic rigid-rod polymers.
tionalized alkylboranes or organic halides. The reaction can be carried out by powdered K$_2$CO$_3$ or $\text{PO}_4$ suspended in DMF at 50 °C in the presence of PdCl$_2$·(dppf) catalyst.\textsuperscript{185,186} Pd(PPh$_3$)$_4$ catalyst works well when aqueous NaOH in benzene or $\text{PO}_4$ in dioxane are used.\textsuperscript{185} The characteristic features of both catalysts are that PdCl$_2$·(dppf) is used well in polar solvents (e.g., THF and DMF), but Pd(PPh$_3$)$_4$ gives good results in nonpolar solvents, such as benzene and dioxane.

One of primary alkyl groups in trialkylboranes participates in the coupling, and the reaction with secondary alkyl is very slow.\textsuperscript{185} Thus, representative hydroboration reagents, such as 9-BBN, disiamylborane, dicyclohexylborane, and borane, can be used as hydroboration reagents for terminal alkenes. However, 9-BBN is most accessible due to its ease of use, high selectivity on hydroboration, and high reactivity on the cross-coupling reaction.

The hydroboration coupling approach for the construction of carbon skeletons affords several advantages (eq 85).\textsuperscript{185} The high stereoselectivity of hydroboration provides a stereodefined alkyl center on boron. The hydroboration occurs chemoselectively at the less hindered C19–C20 double bond. In addition, the alkyl group thus constructed can be readily cross-coupled with alkenyl or aryl halides under mild conditions.

The procedure has been used in a variety of syntheses of natural products,\textsuperscript{186,189} for example, in the synthesis of dihydroxyserullilic acid (Figure 12),\textsuperscript{191} the aggregation pheromone of Cathartus quadriricollis (quadirlure),\textsuperscript{192} and aza-C-disaccharides.\textsuperscript{193} A three-step, three-component synthesis of PGE$_1$ is achieved by utilization of the cross-coupling reaction of 9-alkyl-9-BBN with $\alpha$-iodoenones. It is recognized that cesium carbonate in the presence of water extremely accelerates the coupling reaction carried out at room temperature (eq 86).\textsuperscript{194}

![Figure 12](image_url)

**Figure 12.** Synthesis of dihydroxyserullilic acid.

9-Methyl and 9-[(trimethylsilylmethyl)-9-BBN are easily synthesized by the reaction of the corresponding lithium reagents with 9-methoxy-9-BBN. Unfortunately, such derivatives are spontaneously flammable in air, making them particularly hazardous to handle for isolation. However, selective oxidation with anhydrous trimethylamine N-oxide converts them to air stable borinate esters (eq 87) which are efficient reagents for methylation\textsuperscript{195,196} of haloalkenes or syntheses of allylic and propargylic silanes.\textsuperscript{197} (eq 88)

\[

\end{aligned}
\quad (88)
\]

The intramolecular cross-coupling proceeds especially smoothly when the cyclization results in the formation of either five- or six-membered rings.\textsuperscript{185,186,199} The hydroboration of the terminal double bond with 9-BBN is faster than that of the halogenated double bond, e.g., the relative rate, 2-methyl-1-pentene (196); 1-hexene (100); (Z)-1-bromo-1-butene (0.011). Thus, hydroboration coupling approach provides a new route for stereodefined exocyclic alkenes (eq 89).

Although alkylboronic acids or their esters are quite inert under above conditions, the organoborates are more convenient to use, since they are stable in air and are handled easily for isolation. The cross-coupling of alkylboronates with 1-alkenyl or aryl halides proceeds in moderate yields in the presence of Ti$_2$CO$_3$ and PdCl$_2$(dppf), although the reaction is limitedly used for activated halides having an electron-withdrawing group. A sequence of the Rh(I)-catalyzed hydroboration\textsuperscript{27a} of allyl acetone and the cross-coupling with haloenones produces diketones in 62–69% yields (eq 90).\textsuperscript{200}
Reactions of Organoboron Compounds

Although the cross-coupling reaction with organic halides have been studied predominantly, it has been most recently discovered that trifluoromethanesulfonates (triflates) undergo a clean coupling with organoboron compounds, similar to organostannanes\(^8\) and aluminum\(^202\) and zinc\(^203\) compounds. The triflates are valuable as partners for the cross-coupling reaction, in part due to the easy access from phenols or carbonyl enolates which allow the selective formation of aryl and 1-alkenyl electrophiles.\(^204\) The cross-coupling reaction of organic triflates is previously reviewed.\(^205\)

Although relatively strong bases such as aqueous NaOH and NaOEt in ethanol have been used for the reaction with halides, powdered K$_2$PO$_4$ suspended in THF or dioxane is sufficient enough to accelerate the coupling of 9-alkyl-9-BBN, 1-alkenyl-, and arylboronates or boronic acids with the triflates.\(^206\) Pd(PPh$_3$)$_4$ in dioxane at 65 °C is less effective than PdCl$_2$(dppf) in refluxing THF, but it may give a comparable yield by carrying out the reaction at 80 °C (eqs 91 and 92). The choice of suitable boron reagents effects high yields of products. For arylation of triflates, boronic acids afford better results than the corresponding boronic esters (eq 92), and 9-alkyl-9-BBN derivatives are recommended as the best reagents for alkylation. The catechol esters of 1-alkenylboronic acids usually work more effectively than the corresponding boronic acids and disiamyl or dicyclohexyl derivatives (eq 91).\(^206\)

Although good yields are achieved for five- and six-membered cyclization by the intramolecular cross-coupling reaction of haloalkenes (eq 89), the scope of the reaction is still limited by the availability of haloalkenes, particularly due to the lack of a simple method for preparing cyclic haloalkenes from ketone precursors. The ready availability of triflates from carbonyl compounds now offers a valuable tool for annulation of ketones (eq 93).\(^206\) Since the synthesis of the compounds having a metal and a leaving group in the same molecule is rather difficult by other methods, the hydroboration-coupling approach provides an efficient way for such cyclization via the intramolecular coupling.

The coupling with triflates often fails to proceed due to the decomposition of catalysts, precipitating palladium black at the early stage of reaction.\(^206,207\) Presumably, triphenylphosphine used as a ligand of palladium reacts with triflates to give phosphonium salts (eq 94).\(^208\) Addition of 1 equiv of lithium or potassium bromide is effective in preventing such a decomposition of the catalyst, which is known to convert the labile cationic palladium(I) species to organopalladium(I) bromide.\(^209\) Lithium chloride or potassium chloride is less effective, though LiCl has been used in most cases.\(^184,207\)

\[ R^1B(OH)_2 + 9-BBN \rightarrow \text{product} \]  
\[ \text{eq 92} \]

\[ \text{Me-C-CH} = \text{CH} - \text{CH}_2 \rightarrow \text{Me-C-(CH)}_2\text{B} - \text{Me-C-(CH)}_2\text{B} \]  
\[ \text{eq 90} \]

The order of reactivity of halides and triflates for the cross-coupling reaction of boron reagents is I > Br > OTf and Cl. Thus, the sequential cross-coupling reaction of 4-bromophenyl triflate with two 9-alkyl-9-BBN derivatives, obtained from two different alkenes, furnishes the unsymmetrically disubstituted benzenes. However, an alternative and presumably reliable method to introduce two different organic groups to benzene rings is a stepwise double cross-couplings with iodophenol derivatives (eq 95).\(^101,206\)

\[ \text{Me-C} - \text{OMOM} \rightarrow \text{Me-C} - \text{H} + \text{Me-C} \]  
\[ \text{eq 95} \]

Ready availability of cycloalkenyl triflates from ketone precursors is superior to the synthesis of corresponding halides. The syntheses of arylated cycloalkenones\(^104,210\) and 2-substituted carbapenem (eq 96)\(^211\) have been achieved in excellent yields by the reaction with triflates.

\[ \text{Me-C-O-TES} \rightarrow \text{Me-C-Ph} \]  
\[ \text{eq 96} \]

E. Synthesis of Vinylic Sulfides

1-Alkenyl sulfides are valuable intermediates for the synthesis of ketones or aldehydes by hydrolysis with mercury(I) chloride,\(^212\) the synthesis of 1-alkenyl sulfoxides\(^213\) which can serve as dienophiles in the Diels–Alder reaction or as Michael acceptors, and...
the synthesis of a variety of alkenes and dienes via the nickel-catalyzed cross-coupling reaction\(^{214}\) of the C–S bond with Grignard reagents. However, there are only a few stereoselective syntheses of 1-alkenyl sulfides. The coupling reactions of 1-alkenyl halides with thioalkoxides in the presence of a transition-metal catalyst provide vinylic sulfides in excellent yields with high stereoselectivity.\(^{6,215}\) Another route to vinylic sulfides involves cross-coupling reactions between (β-alkylthio)alkenyl halides and alkyl, aryl, and 1-alkenylmagnesium halides.\(^{214}\) Wittig and related methods unfortunately provide a mixture of stereoisomers.\(^{216}\)

The cross-coupling reaction of 9-(organothio)-9-BBN derivatives (46) with 1-alkenyl and aryl halides proceeds in excellent yields (eq 98).\(^{217}\) The reaction can be carried out under milder conditions than those of analogous reactions using lithium or tin thioalkoxides.

\[
\text{RSH} + 9\text{-BBN} \rightarrow \text{RS-B} \quad (97)
\]

\[
\text{RSH} + 9\text{-BBN} \rightarrow \text{RS-B} \quad (98)
\]

(E)- and (Z)-1-bromo-2-(phenylthio)alkenes (47) are efficient building blocks for the synthesis of stereo-defined 1-alkenyl sulfides by the cross-coupling reaction with organoboron compounds (eq 99).\(^{118,218}\) The sulfides 47 have several advantages in terms of their practical use for cross-coupling reaction. (E)- and (Z)-47 are readily available and most importantly, both stereoisomers are readily separable by chromatography. The rate of coupling with the carbon-bromine bond is reasonably faster than that with the carbon-sulfur bond, which completely avoids the formation of the symmetrical coupling product.

\[
\text{R}^\prime \text{Br} + \text{Pd(PPh}_3\text{)}_4 \text{aq. KOH} \rightarrow \text{R}^\prime \text{B} + \text{PhS} \quad (99)
\]

The sequential double cross-coupling of vinylboronates and vinylvagnesium reagents provides an alternative method for synthesis of conjugated polyenes (eq 99).\(^{118}\) Unfortunately, a mixture of stereoisomers is given on the latter nickel-catalyzed reaction.\(^{214}\) The possibility of improving catalytic conditions has not yet been explored.

The ready availability of 2-(organothio)-1-alkenylboron compounds obtained by catalytic hydroboration of 1-(organothio)-1-alkynes (eq 100)\(^{217}\) or thioboration\(^{92}\) of 1-alkynes (eq 102) now offers more flexible and reliable routes to such stereodefined alkenyl sulfides in combination with the cross-coupling reaction with organic halides.

\[
\text{R}^\prime \text{Br} + \text{Pd(PPh}_3\text{)}_4 \text{aq. KOH} \rightarrow \text{R}^\prime \text{B} + \text{PhS} \quad (100)
\]

The vinylborane 49 has unusually high nucleophilicity due to the activation by an electron-donating β-organothio group. Consequently, protodeboronation proceeds instantaneously with methanol to
provide the thiol adducts regioselectively (eq 103). Although ketones are quite inert to 49, the addition to aldehydes at 50 °C, followed by the mercury(II)-induced hydrolysis gives an enone (eq 105).220

F. Coupling with Iodoalkanes: Alkyl-Alkyl Coupling

Although a wide variety of organic electrophiles, such as aryl, 1-alkenyl, benzyl, allyl, and 1-alkynyl halides, have been utilized for the palladium-catalyzed cross-coupling reactions, it has been considered that such reactions cannot be extended to alkyl halides with sp^3 carbon having β-hydrogens due to the slow rate of oxidative addition of alkyl halides to palladium(0) complexes and the fast β-hydride elimination from α-alkylpalladium intermediates in the catalytic cycle. Thus, the use of alkyl halides as coupling partners is a challenging problem in several recent publications. Although Castle and Widdowson221 had recently reported that Pd(dpp0, formed in situ by the reduction of PdCl_2(dpp0 with DIBm, effectively catalyzes the cross-coupling reaction of iodoalkanes with Grignard reagents, this unique reaction has been denied most recently by Yuan and Scott.222

Among the catalysts we examined for the cross-coupling reaction between 9-alkyl-9-BBN with primary iodoalkanes, the palladium complex with triphenylphosphine as ligand is recognized to be most effective (eq 106).223 The best yield is obtained when

\[
C_{12}H_{25}I + C_8H_5B \rightarrow \begin{array}{c}
Pd(PPh_3)4 \\
K_3PO_4 \\
dioxane, 60 ^\circ C
\end{array}
\]

the reaction is conducted at 60 °C for 24 h by using 3 mol % of Pd(PPh_3)4 and K_3PO_4 (3 equiv) in dioxane. Although PdCl_2(dppf) is reported as a selective catalyst to avoid β-hydride elimination for alkyl couplings, the complex does not act as an efficient catalyst in the present reaction. Other bidentate ligands such as dppe, dpp and dppb also give low yields of coupling products. Such bidentate ligands may retard the step of reductive elimination because the reductive elimination from dialkylpalladium(II) proceeds from an unsaturated, three-coordinated species (eq 25), in contrast to the coupling with aryl or vinyl derivatives which can proceed through a four-coordinated saturated complex (eq 24).57

The difficulty of alkyl-alkyl coupling reaction is mainly due to the formation of alkane at the step of oxidative addition of iodoalkane to Pd(0) complex. The β-elimination during the steps of transmetalation and reductive elimination is a minor process. The formation of reduction products (decane in eq 106) can be mainly due to the involving radical oxidative addition process (see section VI).53

The available results indicate that the cross-coupling reaction of 9-alkyl-, 9-phenyl-, or 9-1-alkenyl)-9-BBN gives 50–60% yields of products when using 50% excess of primary iodoalkanes and higher yields around 80% when using iodomethane (eqs 107 and 108).223

G. Coupling with Other Organic Halides and Boron Reagents

Hydroboration of alkynes with disiamylborane, followed by cross-coupling with allylic or benzylic halides in the presence of Pd(PPh_3)4 and aqueous NaOH produces 1,4-alkadienes or allylbenzenes in high yields.225 In the reaction with 1-bromo-2-butene, the bond formation occurs at two positions (the ratio of straight to branched is 72:28) in accordance with a mechanism involving π-allyl palladium intermediate.225 The reaction has been applied in a short step synthesis of humulene (eq 110).228 The cross-coupling reaction of 1,3-disubstituted allylic carbonates with aryl- and alkenyborates are catalyzed by NiCl_2(dppf), and the reaction proceeds with inversion for the cyclic carbonate (eq 111).227 The stereochemistry indicates the process involving the oxidative addition with inversion and the arylation from the same face of the palladium.

1-Alkenylboranes react with 3,4-epoxy-1-butene in the presence of palladium or nickel complexes to form internal and terminal coupling products with high regioselectivity in same cases (eq 112).71 The ratio of two dienols can be reversed by changing the metal.
complexes. The reaction proceeds under neutral conditions in good agreement with the mechanism through an (alkoxo)palladium(II) complex (20 in eq 32).

\[
\begin{align*}
\text{CH}_2\text{CH}=\text{CH}-\text{CH}_2 & \xrightarrow{\text{Pd(0)-catalyst}} \text{O}^+ \text{Pd}^2+ \\
\text{3a} & \rightarrow R^'\text{CH}=\text{CH}-\text{OH} + R^'\text{CH}CH-\text{CH}_2-\text{OH}
\end{align*}
\]

As discussed in the previous section, propargylic carbonates couple with aryl, 1-alkenyl-, 1-alkynyl-, or alkylboron compounds under neutral conditions using palladium catalyst to provide allenes in high yields (eq 36). A similar coupling reaction of organoboron compounds with 2,3-alkadienyl carbonates produces 2-substituted 1,3-butadiene derivatives in the absence of base (eq 113). The coupling may occur through an (alkoxo)palladium(II) intermediate formed via oxidative addition by S22N type displacement with Pd(O), thus allowing the reaction under neutral conditions.

\[
\begin{align*}
\text{COMe} & \xrightarrow{\text{Pd(PPh}_3)_4} \text{OTBS}
\end{align*}
\]

V. Head-to-Tail Coupling

The reaction of phenyl or 1-alkenyl iodides with 1-alkenyloboronic esters produces the unusual "head-to-tail" cross-coupling products in good yields (eqs 28 and 117) through the mechanism shown in Figure 2.

\[
\begin{align*}
\text{3a} + \text{CH}=\text{CHPh} & \xrightarrow{\text{Pd(OAc)}_2/\text{BPh}_3} \text{PhCH}=\text{CH} \\
\text{EtN (5 equiv)} & \xrightarrow{\text{DMF, 80 °C}} \text{PhCH}CH
\end{align*}
\]

VI. Carbonylative Coupling

Carbonylative cross-coupling reactions of organic halides with organometallic compounds, such as organotin, boron, aluminum, and zinc reagents have been extensively studied and reported to provide excellent methods for the synthesis of unsymmetrical ketones or aldehydes. The general catalytic cycle for this carbonylative coupling reaction is analogous to the direct coupling except that carbon monoxide insertion takes place after the oxidative addition step and prior to the transmetalation step (Figure 13).

Only one example is reported for the cross-coupling reaction of 1-alkenyloboron compounds. Methoxy(alkynyl)borates in situ prepared by addition of 9-methoxy-9-BBN to alkynyllithiums undergo efficient cross-coupling with aryl or 1-alkenyl halides to produce various alkynes (eq 116).

\[
\begin{align*}
\text{MeC(OCH}_3)\text{C}=\text{C}(\text{Me})\text{C}_3 & \xrightarrow{\text{PhI, NaOAc, THF, reflux}} \text{Ph} + \text{MeC}CH=\text{C}(\text{Me})\text{C}_3
\end{align*}
\]
Among a variety of organometallics, organoboron compounds were first used by Kojima for the synthesis of alkyl aryl ketones (eq 120). The action of Zn(acac)₂ in this reaction is ascribed to the formation of RCOPOd(acac) species (eq 121) which undergoes transmetalation without assistance of bases (eq 32).

\[
\text{1} + \text{CO} + \text{ArX} \xrightarrow{\text{PdCl}_2(\text{PPh}_3)_2, \text{THF} - \text{HMPA}, 50^\circ \text{C}} \text{R-CO} - \text{Ar} \quad (120)
\]

\[
\text{51} + \text{Zn(acac)}_2 \xrightarrow{\text{Zn(acac)}_2, \text{THF} - \text{HMPA}, 50^\circ \text{C}} \text{R-CO} - \text{Ar} \quad (121)
\]

A general carbonylative cross-coupling can be readily carried out using K₂CO₃ or Cs₂CO₃ as a base. Alkyl 1-alkenyl and alkyl aryl ketones are synthesized by the reaction of 9-alkyl-9-BBN with 1-alkenyl or aryl iodides in the presence of Pd(PPh₃)_4 and K₂CO₃ (eq 122). For the synthesis of biaryl ketones, the cross-coupling reaction between arylboronic acids, carbon monoxide, and iodoarenes in anisole takes place at 80 °C in the presence of PdCl₂(PPh₃)₂ and K₂CO₃ (eq 123). The hydroboration-carbonylative coupling sequence is extended to intramolecular reaction to afford cyclic ketones (eq 124). The ate complexes obtained from α-lithioindoles and triethylborane are carbonylated and coupled with aryl iodides, alkynyl iodides, or cycloalkenyl triflates to provide a simple route to 2-indolyl ketones (eq 125).

\[
\text{OMOM} \xrightarrow{\text{CO (1 atm)}} \text{Pd(PPh}_3)_4/\text{K}_2\text{PO}_4/\text{benzene, rt} \quad (122)
\]

\[
\text{OMOM} \xrightarrow{\text{1, 9-BBN}} \text{OMOM} \quad (123)
\]

\[
\text{OMOM} \xrightarrow{\text{2, CO (1 atm), PdCl}_2(\text{PPh}_3)_2/\text{K}_2\text{PO}_4/\text{benzene, rt}} \quad (124)
\]

Although the reaction works well for iodoarenes and 1-iodo-1-alkenes having electron-donating groups, the application to the electron-deficient iodides is severely limited due to the side reaction forming direct coupling products without carbon monoxide insertion (Figure 13, path A). Namely, the presence of an electron-withdrawing group retards the insertion of carbon monoxide into the R_Pd(I)X intermediates, and it reversely accelerates the rate of transmetalation to generate the R-Pd²⁺-R' species. The use of carbon monoxide under high pressure is a general method for suppressing such a side reaction. Another efficient procedure involves the control of the rate of transmetalation to be sufficiently slower than that of carbon monoxide insertion by changing the organometallic reagents. The reaction of organoboron reagents can be controlled by choosing an appropriate base and a solvent to permit the selective coupling even under an atmospheric pressure of carbon monoxide (eq 126).

\[
\text{Me-C} \xrightarrow{\text{PhB(OH)}_2/\text{CO (1 atm)}} \text{Me-C} \quad (126)
\]

The use of organic iodides is essential to achieving high yields. Organic bromides provide appreciable amounts of direct coupling products since the transmetalation of 50 (X = Br) with organoboron reagents is faster than the corresponding iodides (path A in Figure 13). In all of these reactions, some of the carboxylic acid derivatives formed from path B can be commonly observed. The cross-coupling reaction has been currently developed; however, such reactions are limitedly applicable to 1-alkenyl, 1-alkynyl, aryl, allyl, and benzyl halides and not being extended to alkyl halides with sp³ carbon containing β-hydrogen, as discussed in the previous section. The problem of β-hydride elimination is not serious in the carbonylation reaction because the insertion of carbon monoxide converts them to the acylpalladium(II) halides. Thus, various iodoalkanes including primary, secondary, and tertiary iodides are carbonylated and coupled with 9-R-9-BBN in the presence of K₂PO₄ and a catalytic amount of Pd(PPh₃)₄ yielding unsymmetrical ketones in good yields (eq 127). The reaction is extremely accelerated by irradiation of sunlight.

\[
\text{55} \quad (127)
\]

A particularly interesting feature in this transformation is that oxidative addition proceeds through the radical process; presumably, it is initiated by an electron transfer from palladium(0) complex to iodoalkanes to form a radical pair (Pd'X + I⁻). Thus, the iodoalkanes provides cyclized ketones via a sequence of radical cyclization, carbon monoxide insertion, and the coupling with 9-R-9-BBN (eqs 128 and 129). The cyclization is generally not stereoselective, but the reaction of 55 proceeds with high endo selectivity due to the anomeric effect which favors the transition state (56) shown in eq 129. As isocyanides are isoelectronic with carbon monoxide, they might be expected to exhibit a similar insertion reaction. However, they have not been used for the cross-coupling reaction. The difficulty is mainly due to its tendency to cause multiple insertions to transition metal complexes leading to poly-
isocyanides. The 9-alkyl-9-BBN reacts with isocyanide to form a relatively stable 1:1 complexes which readily participates in the cross-coupling reaction catalyzed by palladium. The complexes are successfully used for the iminocarbonylative cross-coupling reaction of 9-alkyl-9-BBN derivatives with haloarenes (eq 130).245

VII. Alkoxycarbonylation and Dimerization

Unlike the cross-coupling reaction discussed above, the palladium-catalyzed alkoxycarbonylation of organoboron compounds proceeds through the transmetalation of organic group on boron to palladium(II) atom, CO insertion into the C-Pd bond, and finally the reductive elimination to the products and Pd(0). Thus, suitable reoxidants of palladium(0) to palladium (II) are required to recycle the palladium catalyst (Figure 14). p-Benzoquinone in the presence of LiCl selectively oxidizes the palladium(0) complex in the presence of aryl- or 1-alkenylboronic esters.246

Under atmospheric pressure of carbon monoxide, 1-alkenylboronates are carbonylated at 50 °C in the presence of PdCl2, NaOAc, p-benzoquinone, and LiCl in methanol (eqs 131 and 132).247 The stereochemistry of 1-alkenylboronates can be retained over 99%. The hydroboration–carbonylation sequence cleanly provides terminal esters in contrast to the direct alkoxycarbonylation of terminal alkynes with carbon monoxide and alcohol in the presence of transition-metal catalyst.

In the presence of a catalytic amount of Pd(OAc)2 and Cu(OAc)2 as a reoxidant, 1-alkenylboronates readily dimerize in methanol to give symmetrical dienes (eq 133). Although the blank test indicates that the dimerization proceeds to some extent in the absence of palladium catalyst, a few mole percent of Pd(OAc)2 may greatly improve the yield of diene. Symmetrical biaryls can also be obtained from arylboronic acids.

VIII. Conclusion

The cross-coupling reaction of organoboron reagents with organic halides or related electrophiles represents one of the most straightforward methods for carbon–carbon bond formation. The reaction proceeds under mild conditions, being largely unaffected by the presence of water, tolerating a broad range of functionality, and yielding nontoxic byproducts. Consequently, the cross-coupling reaction of organoboron reagents has been realized in significant and diverse applications not only in academic laboratories but also in industries. In view of retrosynthetic analysis, the reaction is conceptually basic and important for construction of carbon framework of target molecules. The scope of the palladium-catalyzed cross-coupling reaction of the representative organoboron compounds with organic halides are summarized in Figure 15.

A very wide range of aryl- and 1-alkenylboron reagents undergo the palladium(0)-catalyzed reactions with alkyl, allylic, 1-alkenyl, aryl, and 1-alkynyl substrates. Allylic halides react with aryl- and 1-alkenylboron reagents, but alkyl- and allylboron reagents fail to give the corresponding coupling products; presumably because the reductive elimination from α-alkyl-α-allyl- or α-α-allylpalladium(II) complexes is very slow to develop the catalytic
Since the palladium-catalyzed cross-coupling reaction of alkylidene metals or halides often suffers from poor regioselectivity, the corresponding cross-coupling reaction of organocopper reagents can be a more general alternative. Primary iodoalkanes couple with alkyl-, 1-alkenyl-, and arylboron reagents, but secondary and tertiary iodoalkanes are limitedly used. The Sonogashira reaction is more convenient in most cases.
