Abstract

Clostridium botulinum type D strain OFD05, which produces the D/C mosaic neurotoxin, was isolated from cattle killed by the recent botulism outbreak in Japan. The D/C mosaic neurotoxin is the most toxic of the botulinum neurotoxins (BoNT) characterized to date. Here, we determined the crystal structure of the receptor binding domain of BoNT from strain OFD05 in complex with 3'-sialyllactose at a resolution of 3.0Å. In the structure, an electron density derived from the 3'-sialyllactose was confirmed at the cleft in the C-terminal subdomain. Alanine site-directed mutagenesis showed the significant contribution of the residues surrounding the cleft to ganglioside recognition. In addition, a loop adjoining the cleft also plays an important role in ganglioside recognition. In contrast, little effect was observed when the residues located around the surface previously identified as the protein receptor binding site in other BoNTs were substituted. The results of cell binding analysis of the mutants were significantly correlated with the ganglioside binding properties. Based on these observations, a cell binding mechanism of BoNT from strain OFD05 is proposed, which involves cooperative contribution of two ganglioside binding sites.

Keywords

botulinum neurotoxin, D/C mosaic, receptor binding domain, crystal structure, ganglioside recognition

Introduction

From recent outbreaks of botulism in cattle farms in Japan, *Clostridium botulinum* strain OFD05 was isolated from feces specimens [1]. It produces a DC mosaic botulinum neurotoxin (BoNTs). Genetic analysis of the toxin showed that it consists of two thirds of type D neurotoxin (BoNT/D) and one third of type C neurotoxin (BoNT/C) [1,2]. Moreover, it showed the highest lethality in mice following intraperitoneal injection (1.1×10^9 LD₅₀/mg protein) compared with other types of BoNT. Structurally, the activated mature toxin consists of three functionally distinct modules: the light chain with Zn²⁺-dependent metalloprotease activity and the heavy chain that encompasses the N-terminal 50-kDa translocation domain (H_N), and C-terminal 50-kDa receptor binding domain (H_C) [3,4,5]. These modules work cooperatively to ensure successful intoxication to the target presynaptic neuron cell. A two-receptor model has been proposed as the initial binding step using the H_C domain of BoNTs, in which the H_C domain recognizes both ganglioside and protein receptor [6,7,8]. These complex structures of BoNT_H_C and its receptors revealed that BoNTs use a structurally conserved site, *i.e.*, the ganglioside binding site (GBS), to recognize ganglioside, in which the peptide motif SXWY is conserved among the majority of BoNTs examined to date [4,9]. For the protein receptor, the structure of BoNT/B was determined in the complex form with synaptotagmin-II (Syt-II) (PDBID 2NM1), which showed that the protein binding site (PBS) lies next to the ganglioside binding site (GBS) separated by a loop region [10]. Based on these structures, a model in which ganglioside and protein receptor are recognized individually at GBS and PBS, respectively, was proposed for the two-receptor model [9,10].

There have been some interesting recent reports regarding BoNTs that cause animal botulism, *i.e.*, type C, type D, and the D/C mosaic type. Strotmeier *et al.* reported that both GBS and PBS are used for ganglioside binding in type D lacking the SXWY motif [11]. In addition, Karalewitz *et al.* reported that a loop located between PBS and GBS (the ganglioside binding loop, GBL) contributes markedly to ganglioside recognition by type C, which also lacks the SXWY motif [12]. However, there have been no previous reports regarding these BoNTs in which the functions of each site, *i.e.*, the PBS, GBS, and the loop between them, were evaluated by an identical method. In the present study, we compared the contributions of these regions in the H_C domain of BoNT from strain OFD05 (OFD05H_C) on ganglioside and cell binding. First, we obtained crystal structures of OFD05H_C in apo and complex forms with 3'-sialyllactose, which defined GBS, PBS, and GBL. Then, we constructed alanine-substituted mutants based on the crystal structure, and evaluated ganglioside binding by SPR and P19 cell

binding assay. Based on the results, we propose a receptor binding mechanism of OFD05H_C, which utilizes ganglioside as its receptor at the classical GBS with auxiliary contributions from GBL.

Materials and Methods

Expression, purification, and crystallization

1.1 Preparation and crystallization of OFD05H_C

Expression and purification of OFD05H_C (residues E859 – E1285) were described previously [13]. The crystals of OFD05H_C that were used for further X-ray diffraction analysis were grown with 100 mM MES (pH 6.5) and 1.6 M magnesium sulfate.

1.2 Crystallization of OFD05H_C in complex with 3'-sialyllactose

The expression vector was prepared with a KOD-Plus Mutagenesis Kit (Toyobo, Osaka, Japan) using synthesized primers (Supplementary Table 1) and plasmid constructed previously [13]. The later steps including expression and purification were conducted using the same procedures as described previously [13]. After concentrating protein to 3 mg/ml, 3'-sialyllactose (Sigma-Aldrich, St. Louis, MO) was added at a final concentration of 5 mM. The mixture was incubated at 293 K for at least 30 min, and then used for crystallization. The best crystal of OFD05H_C in complex with 3'-sialyllactose was grown from a mother liquor containing 100 mM MES (pH 6.5), 1.6 M magnesium sulfate, and 1 M sodium chloride.

Data collection and structure determination

X-ray diffraction data were collected at the synchrotron facilities of Spring-8 (Hyogo, Japan) and Photon Factory (Tsukuba, Japan).

X-ray diffraction data of OFD05H_C and in complex with 3'-sialyllactose were collected at resolutions of 3.1 and 2.99 Å, respectively (Table 1). Diffraction data were processed, integrated, and scaled using the programs HKL2000 [14] and XDS [15]. The crystal structures were determined by the molecular replacement method with the program MOLREP [16] in the CCP4 program package [17] using the structure of BoNT/D-South Africa H_C (PDB ID 3N7L) as a search model. The model was constructed manually using the program COOT [18]. Positional and B-factor refinement were carried out with the programs REFMAC5 [19] and Phenix [20,21]. Finally, 836 residues (from two molecules) and 27 water molecules were placed in the structure of OFD05H_C with crystallographic R and R_{free} values of 24.4% and 28.9%, respectively. For OFD05H_C in complex with 3'-sialyllactose, 836 residues and 12 water molecules could be constructed with R and R_{free} values of 25.0% and 29.2%, respectively.

Preparation of mutants

Site-directed mutants were constructed by QuikChange site-directed mutagenesis (Stratagene, La Jolla, CA). The primers used for construction of the mutants are listed in

Supplementary Table 1. These mutants were induced for heterogeneous protein expression in *Escherichia coli* under the same conditions as the wild-type OFD05H_C [13]. After cell disruption, the supernatant was purified by a Ni-NTA agarose column (Qiagen, Germantown, MD). Fractions containing the target protein were collected and dialyzed against 20 mM Tris-HCl (pH 8.0) and 200 mM NaCl.

Surface Plasmon Resonance

POPC (1-palmitoyl-2-oleoyl-*sn*-glycero-3-phosphocholine) (5 μ mol) in chloroform was mixed with 1 mol% ganglioside GM1a, GD1a, and GQ1b from bovine brain in chloroform/methanol mixture (1:1 by volume) and dried to a thin film under nitrogen gas using an evaporator. The lipid film was hydrated with addition of 0.5 mL of phosphate buffered saline by vortexing for 3 min to yield 10 mM solution with respect to POPC. After freeze-thawing five times, the suspension was extruded 20 times through a 50 nm filter. As a negative control, liposomes were also prepared from POPC alone. Immobilization of liposomes on the L1 sensor chip (GE Healthcare, Waukesha, WI, USA) and all measurements of SPR were performed using a Biacore 2000 (GE Healthcare). The immobilized sensor chip was primed with 10 mM HBS-N. Each analyte (OFD05H_C and its mutants, 500 nM) in HBS-N was injected for 2 min at a flow rate of 30 μ L/min. After dissociation with the same buffer for 2 min, the chip was regenerated with a 1-min injection of 1 mM NaOH to remove the residual H_C on the surface and then replaced with HBS-N for use in subsequent cycles. The sensorgram of the binding of POPC alone was subtracted from that of POPC containing ganglioside as nonspecific binding.

Fluorescence Immunocytochemistry

P19 embryonal carcinoma cells were kindly provided by Dr. T. Ohkawara (Mie University, Mie, Japan). The cells were cultured and induced to differentiate into neuronal cells using the procedures described previously [22,23]. The cells were treated with or without 50 nM H_C for 30 min at 37°C, and washed three times with 1 mL of culture medium. The cells were fixed in 4% paraformaldehyde/phosphate buffered saline for 15 min at room temperature. The fixed cells were permeabilized with phosphate buffered saline containing 0.1% Triton X-100 for 5 min at room temperature. After three rinses with phosphate buffered saline containing 10 mM glycine, the cultures were incubated with phosphate buffered saline containing 3% bovine serum albumin (BSA). For detection of intracellular H_C, the cells were incubated with rabbit polyclonal anti-OFD05H_C antibody (5 μ g/mL) for 30 min at room temperature. After

washing with phosphate buffered saline – 0.1% BSA, the cells were incubated with Alexa Fluor® 488-conjugated anti-rabbit IgG (1:500) (Invitrogen) for 30 min at room temperature. After washing with phosphate buffered saline – 0.1% BSA, the cells were mounted on slide glasses with ProLong® Gold Antifade reagent (Invitrogen). Immunoreactive cells were visualized under an LSM 710 confocal microscope (Zeiss, Oberkochen, Germany). Fluorescence intensity was measured with ZEN2009 software (Zeiss).

Results

Crystal structure of OFD05H_C in complex with 3'-sialyllactose

The crystal structure of OFD05H_C in the presence of 3'-sialyllactose (α -NeuNAc-(2 $\rightarrow$ 3)- β -D-Gal-(1 $\rightarrow$ 4)-D-Glc) was determined by the molecular replacement method at a resolution of 2.99 Å (Fig. 1A). Based on structure comparison with BoNT/A in complex with GT1b and BoNT/B with Syt-II, the ganglioside binding site (GBS), the protein receptor binding site (PBS), and a long ganglioside binding loop (GBL) were defined (Fig. 1A and 1D). In one of two molecules contained in an asymmetric unit, a substantial electron density was observed in the GBS surrounded by N1114, I1240, G1241, Y1243, and L1270 (Fig. 1B). In contrast, no electron density was found at the corresponding site of the other molecule. The structural superposition of BoNT/A – GT1b complex showed that the electron density overlapped onto the GT1b in the structure of BoNT/A (Fig. 1C), suggesting that the observed electron density corresponds to bound 3'-sialyllactose. However, we could not construct a model of 3'-sialyllactose, as the observed electron density was too small and ambiguous. In addition, a sulfate ion was bound at the tip of the GBL, with which F1251, W1252, Y1253, and H1255 made interactions.

To confirm that the observed electron density was derived from 3'-sialyllactose, crystals of apo form OFD05H_C was prepared under similar conditions in which MES buffer and magnesium sulfate were used, and the structure was determined at a resolution of 3.1 Å. No electron density was observed around the GBS, although the structures of OFD05H_C were quite similar (RMSD 0.29 and 0.62 Å over 418 C α atoms for two molecules in an asymmetric unit, respectively). These results confirmed that the electron density observed in the complex structure was derived from 3'-sialyllactose. The side chains as well as the main chains around GBS of the apo and complex forms were superposed well, suggesting that no major structural changes occurred after binding with 3'-sialyllactose. In the structure of the complex with 3'-sialyllactose, a sulfate ion was bound at the tip of the GBL.

Mutation analysis for ganglioside binding

The crystal structure of OFD05H_C in complex with 3'-sialyllactose showed that OFD05H_C captures sugar parts of ganglioside at the GBS. In addition, a unique ganglioside binding mechanism using the GBL located between GBS and the PBS was proposed for the H_C region of BoNT/C. In addition, Strotmeier *et al.* recently reported that in the BoNT/D, the PBS as well as GBS acts as the ganglioside recognition site [11]. In the case of BoNT/C or BoNT/DC, however, the contributions of these individual

regions to receptor binding have not been compared with each other. To evaluate them, 23 alanine-substituted mutants were prepared and their ganglioside binding activities were evaluated by surface plasmon resonance (SPR). The constructed mutants were categorized into three groups: *i.e.*, mutations around GBS, GBL, and PBS.

Ten mutants with mutations around GBS were prepared, and we examined the binding of three types of ganglioside (Supplementary Fig 1A and 2). In all mutants, significant decrease in the binding activity was observed statistically. G1241A, N1114A, I1240A, L1270A, Y1243A, and L1190A showed marked decreases in activity (Fig 2). Even in other mutants, *i.e.*, S1269A, K1263A, and S1242A, the SPR signal was decreased to approximately 60% of that in the wild-type. It should be noted that mutation of residues located adjacent to the electron density in the structure of OFD05H_C – 3'sialyllactose complex, *i.e.*, G1241A, N1114A, I1240A, Y1243A, and L1270, caused significant decreases in the activity (Fig. 1B). These results indicated that GBS in OFD05H_C contributes strongly to ganglioside binding similar to other BoNTs. Similar tendencies were confirmed for all types of ganglioside examined (GM1a, GQ1b, GD1a) (Fig. 2), although the degree of decrease in the activity for GQ1b was smaller than the others.

For mutations in GBL, three alanine-substituted mutants of the residues located at the tip of the loop, F1251A, W1252A, and F1253A, were constructed (Supplementary Fig 1B). In addition, a mutant in which the loop region from Ser1244 to Glu1256 was replaced by two glycine residues (ODF05H_C-Δloop) was prepared. In all of these mutants, marked decreases in binding activity for all types of ganglioside were observed (Fig. 2, which are all statistically significant), although 3'-sialyllactose was not found around this region in the crystal structure. Instead, a sulfate ion was found at the GBL position in both crystal structures.

As mutations in PBS, ten residues were mutated based on the structural alignment between OFD05H_C and BoNT/B – Syt-II (Supplementary Fig. 1C and 3), which are the structural counterparts of the residues of BoNT/B that interact with Syt-II. SPR analyses indicated that all of the alanine substituted mutants showed binding activity for all types of ganglioside, although those of G1124A, G1126A, and P1192 were approximately half those of the wild-type (Fig. 2). Although all mutants other than Y1175A showed statistical difference, the effects of substitutions of PBL are obviously weaker than those for GBS and/or GBL. These results indicated that OFD05H_C does not recognize ganglioside with PBL.

P19 cell binding activity of the mutants

Crystal structure and SPR analysis showed that OFD05H_C recognizes ganglioside using

GBS and GBL, but PBL does not contribute strongly. To explore the contributions of these regions to ganglioside binding *in vivo*, the binding of each mutant for P19 cells was evaluated (Fig. 3).

All mutants of GBL showed markedly reduced cell binding activity, suggesting the importance of this region for cell binding as well as ganglioside recognition. In addition, mutants in GBS, with the exception of S1242A, K1263A, S1269A, and S1273, showed remarkable decreases in the cell binding activity. It should be noted that similar results were also obtained in SPR analysis. In contrast, the activities of the mutants for PBS other than P1192A were comparable to that of wild-type, which also showed a significant correlation with the results of SPR. P1192A showed a fluorescent signal that was approximately 60% of wild-type. Taken together, all mutants that showed a significant decrease in ganglioside binding activity in SPR also showed a marked decrease in cell binding. Therefore, we concluded that the results of cell binding assay are strongly correlated with those of ganglioside binding activity as determined by SPR.

Discussion

The crystal structure of OFD05H_C in the presence of 3'-sialyllactose showed substantial electron density around GBS, although the model of 3'-sialyllactose could not be constructed due to its incomplete shape. The electron density was not observed in the reference crystal of OFD05H_C, which did not contain 3'-sialyllactose. In addition, substitution of the residues located around the electron density markedly diminished the ganglioside binding activity (N1114A, I1240A, G1241A, Y1243A, and L1270A in Fig. 2). In particular, the inactivation of N1114A was the most significant among the constructed mutants. Moreover, the effect was observed for all types of ganglioside examined, whereas other mutants showed only residual activity for GQ1b. Based on these observations, we concluded that the electron density was derived from the 3'-sialyllactose, and the GBS in OFD05H_C recognizes the sugar part of gangliosides similar manner to other BoNTs. It should be noted that the SXWY motif is not conserved in the GBS of OFD05H_C, unlike other BoNTs. Although the absence of the motif in the GBS was also reported for BoNT/D, it has ganglioside binding properties distinct from OFD05H_C, in which both GBS and PBS are present.

Mutations of the GBL resulted in marked inactivation of binding for all types of ganglioside, as well as P19 cells, indicating the importance of the GBL. Karalewitz *et al.* also recently reported the contribution of W1252 located at the tip of the GBL to ganglioside binding [12]. Our results showed that not only W1252, but also the adjacent residues and the entire loop region are also important for receptor binding. Although the mutation in GBL strongly affected the binding of all gangliosides, there was no electron density of 3'-sialyllactose around the GBL. The GBL thus appears to recognize a part that is not contained in the 3'-sialyllactose but is common to all gangliosides, such as the hydrophilic part of ceramide. Interestingly, sulfate was found at the GBL regardless of the conditions used for crystal growth. The sulfate ion was also bound in the same site of BoNT/D, and therefore it was proposed that this loop was bound to the negatively charged phospholipid membrane surface [24]. However, our results excluded this hypothesis for OFD05H_C, because a significant signal was not found in the reference flow cell in the SPR experiment in which the lipid bilayer is immobilized. If the GBL can bind with the hydrophilic head group of the phospholipid membrane surface, a binding signal should be observed in the reference cell. As described above, the GBS is likely to bind directly to the ganglioside. The distance between the electron density of 3'-sialyllactose and the tip of the loop is approximately 30 Å. The GBL would come close to the GBS to form a ganglioside binding site, when OFD05H_C recognizes ganglioside. As substitution into either GBS or GBL resulted in a marked decrease in

ganglioside binding, these two regions are likely to act in a cooperative manner. However, in the case of GQ1b binding, weak activity was observed for mutants of the GBS, instead of the marked inactivation in the mutants of GBL. The contribution of the GBL may be more significant than that of GBS. In contrast to the GBS and GBL, the effects of mutations in the PBS did not cause serious inactivation of binding with either ganglioside or P19 cell, although slight decrease was observed in several mutants such as G1124A, G1126A, P1192A and I1259A. As PBS and GBS are located back to back, these mutants may affect structural flexibility and/or integrity of the GBS. Taken together, we concluded that OFD05H_C recognizes gangliosides using the GBS and GBL, and that the PBS does not make a major contribution.

The results of SPR and P19 cell binding assay were correlated strongly with each other. That is, mutants that showed a significant decrease in ganglioside binding activity on SPR analysis also showed a marked decrease in cell binding, and those with ganglioside binding activity in SPR also had cell binding activity. These results indicated that ganglioside recognition governs binding to the cell. Moreover, the GBS and GBL of OFD05H_C contributed to ganglioside recognition in a cooperative manner, which is a unique property of BoNT/C. In other BoNTs with the exception of BoNT/D, gangliosides are recognized only by GBS, and PBS is responsible for binding to the protein receptor [9,10,25,26,27]. In BoNT/D, both GBS and PBS recognize gangliosides [11]. Moreover, the function of GBL has not been reported for other BoNTs. As mentioned above, BoNT/C and BoNT/D do not possess the SXWY motif and have unique ganglioside binding properties, whereas other BoNTs possessing the SXWY motif capture gangliosides using only GBS. BoNT/C may have developed the ganglioside binding mechanism to overcome the absence of the SXWY motif, and thus have obtained a unique cell binding mechanism in which both GBS and GBL are used for ganglioside recognition.

Acknowledgments

A. BoNT/B_Hc + Syt-II

B. OFD05Hc

Supplementary figure 1. Mutated residues of OFD05H_C located around the GBS (A), GBL (B), and PBS (C). (A) Substituted residues located around the GBS including five residues adjacent to the ambiguous electron density and five candidates from superposition with the H_C of BoNT/A are shown as sticks. The Fo#-Fc map derived from the 3'-sialyllactose is also shown. (B) Mutated residues located in the GBL. Three residues replaced by alanine are shown as sticks, and the region replaced by a linker (S1244#-E1256) is shown as pink ribbons. (C). Mutated residues located around the PBS are shown as sticks. A cartoon model of Syt-II obtained by superposing BoNT/B## Syt-II complex onto OFD05H_C is also shown.

Supplementary figure 2. Superposition of BoNT/A_H_C and OFD05H_C at GBS. Eight crucial residues for BoNT/A and GT1b recognition are shown (A). Structurally corresponding residues in OFD05 are shown (B).

Supplementary figure 3. Superposition of BoNT/B_H_C and OFD05H_C at PBS. Thirteen crucial residues for BoNT/B and Syt-II recognition are shown. Syt-II is shown as transparent ribbon model in both BoNT/B and OFD05 model.
