Magnetic chromatography is an effective system for fine magnetic particle separation because of its strong magnetic field gradients. We have been developing the magnetic chromatography system to separate two or more kinds of fine magnetic particle with different sizes. To evaluate the performances of our developed system, we have also developed a simulation code with taking into account the fluid dynamics and magnetics. It is, however, difficult to consider two or more kinds of fine magnetic particles with different sizes in the simulation, because magnetic interferences between two or more kinds of magnetic particles need to be considered. Therefore, we have newly developed a simulation code to deal with magnetic interferences between two or more kinds of fine magnetic particles.

Index Terms—Magnetic chromatography, magnetic fluid, magnetic particle separation, numerical analysis.

I. INTRODUCTION

MAGNETIC SEPARATION is a useful system for separating fine magnetic particles because of its strong magnetic field gradients in a very small flow channel. Therefore, various magnetic separation systems have been designed, developed and demonstrated [1]–[4]. We have also developed a magnetic chromatography system in order to separate the fine magnetic particles and ions [5]–[7]. In a developed magnetic chromatography system, ferromagnetic wires width of 200 μm , that generate the magnetic field gradients, are located on the upper and lower walls. We had expected that the large particles with a large magnetic susceptibility were extracted in a radial direction of the flow channel and concentrated around the channel wall, and the particles with a small magnetic susceptibility could pass through the channel with weak attraction to the channel wall. In order to confirm the magnetic force attracting for the wall and flow of the fine magnetic particles, we have developed a simulation code coupling the fluid dynamics and magnetics [8].

Some simulation results coupled electromagnetics and fluid dynamics have been reported for various applications [9]–[12]. Some designs of magnetic separation were performed based on a calculation of the magnetic field gradients, not considering the fluid flow [1]. The fluid flow was simulated based on the 2D fluid dynamics analysis coupling with a simplified magnetic field analysis [6], [7]. The simplified magnetic field analysis was conducted only once as a precondition, though the time-varying concentration of magnetic particles affects the magnetic field and its gradients. Hence, to accurately simulate the magnetic fluid flow for magnetic separation, we have developed the 3D simulation code taking into account the Navier-Stokes, control volume, and magnetic field equations simultaneously [8]. The Navier-Stokes equation can represent a fluid flow. The concentration of magnetic particles considering its diffusion is represented by the control volume equation. The magnetic field has to be

solved since its gradients changes as a concentration of the magnetic particles changes. We have confirmed that the developed simulation results adequately agreed with the experimental results [8].

We could not obtain the magnetic separation against the magnetic particles which have different sizes by previously developed simulation code, since it was capable handle with only one kind of magnetic particle. To deal with two or more kinds of magnetic particle with different sizes the volume control and the magnetic field simulations are modified.

II. NUMERICAL ANALYSIS FOR TWO KINDS OF PARTICLES

A. Magnetic Field Analysis

The magnetic fluid would receive magnetic forces based on magnetic field gradients. Therefore, in the simulation to study the behaviors of the magnetic fluid, the magnetic field characteristics with high accuracy have to be considered. However, a scale of magnet is much larger than that of magnetic fluid, because a superconducting magnet, whose scale is large enough, is usually employed to generate a high magnetic field. In this study, the magnetic moment method is employed since the integral method is more accurate than the domain method, such as the finite element method.

Using the magnet moment method [13], the magnetization $\mathbf{M}$ is obtained from

$$-\frac{1}{4\pi} \int_V (\nabla' \cdot \mathbf{M}(\mathbf{r}')) \frac{\mathbf{r} - \mathbf{r}'}{|\mathbf{r} - \mathbf{r}'|^3} dV' + \frac{1}{4\pi} \int_S (\mathbf{M}(\mathbf{r}') \cdot \mathbf{n}) \frac{\mathbf{r} - \mathbf{r}'}{|\mathbf{r} - \mathbf{r}'|^3} dS' - \frac{1}{\chi_m(\mathbf{r})} \mathbf{M}(\mathbf{r}) = -\mathbf{B}_F(\mathbf{r}) \quad (1)$$

where $\mathbf{r}$ and $\mathbf{r}'$ are the position vector, χ_m the susceptibility, and $\mathbf{B}_F$ the magnetic field generated by the magnet, respectively. The magnetic field $\mathbf{H}$ is calculated from the following relation;

$$\mathbf{H} = \frac{1}{\mu_0 \chi_m} \mathbf{M} \quad (2)$$

where μ_0 is the permeability in the free space.

In the magnetic field analysis, it is assumed that the magnetization $\mathbf{M}$ of the particles is parallel to the magnetic field $\mathbf{H}$ and angular momentum of the particles can be ignored. The magnetization of the magnetic particles is generally given by [14]

$$\mathbf{M} = \phi M_s L\left(\frac{\mu_0 m |\mathbf{H}|}{kT}\right) \frac{\mathbf{H}}{|\mathbf{H}|} \quad (3)$$

where ϕ is the concentration of the magnetic particles, M_s the saturation magnetization, L the Langevin function, k the Boltzmann constant, T the absolute temperature, and $m = V_p M_s$, where V_p is the volume of a magnetic particle. The magnetic susceptibility is dependent on the size of magnetic particle, but in this study, the magnetic field is so strong that the Langevin is equal to 1.0.

In order to deal with two or more kinds of magnetic particles, the magnetization $\mathbf{M}^{(e)}$ of the element e is defined as

$$\mathbf{M}^{(e)} = \frac{\mathbf{H}}{|\mathbf{H}|} \sum_{i=1}^n \phi_i M_{si} \quad (4)$$

where n is the number of kinds of magnetic particle. That is, the magnetization is represented as the summation of the magnetization of each particle, and the orientation of the magnetization is the same as that of the magnetic field. The concentration ϕ_i is given by solving the control volume equation.

The tetrahedral element is employed for solving (1) by the magnetic moment method.

B. Control Volume Analysis

To compute the concentration ϕ_i of i -th kind of the magnetic particle, the governing equation is as follows;

$$\frac{\partial}{\partial t}(\rho \phi_i) + \nabla \cdot (\rho \mathbf{v} \phi_i) = \nabla \cdot (\Gamma \nabla \phi_i) + S \quad (5)$$

where ρ , $\mathbf{v}$, Γ , and S are the fluid density, the fluid velocity, the scalar diffusion constant, and the scalar source term, respectively. Equation (5) is solved independently in every kind of the magnetic particle. The fluid velocity $\mathbf{v}$ is given by the Navier-Stokes equation.

The ordinary finite element method with the common tetrahedral element is employed for solving (5) in this study.

C. Navier-Stokes Analysis

The governing equation of the fluid flow is

$$\rho \frac{\partial \mathbf{v}}{\partial t} + \rho \mathbf{v} \cdot \nabla \mathbf{v} = -\nabla p^* + \mu_0 (\mathbf{M} \cdot \nabla) \mathbf{H} + \eta \nabla^2 \mathbf{v} \quad (6)$$

where p^* and η are the composite pressure and the coefficient of viscosity, respectively. The magnetization $\mathbf{M}$ and the magnetic field $\mathbf{H}$ are obtained from solving (1)-(4).

The Navier-Stokes equation is solved by the stabilized finite element method, that is the streamline upwind/Petrov-Galerkin and Pressure stabilizing/Petrov-Galerkin method, popular in the field fluid dynamics simulation [15].

D. Magnetic Fluid Flow Analysis for Magnetic Separation

For simulation of the magnetic separation, two or more kinds of magnetic particles have to be taken into account, however it is impossible to simulate it by any commercial software. Therefore, we have developed the simulation code to deal with two or more kinds of magnetic particles, solving (1)-(6). Fig. 1 shows the flowchart of the developed simulation, the magnetic field, the Navier-Stokes, and the control volume analyses are done sequentially.

FIG. 1 HERE

The tetrahedral elements are commonly used in the magnetic field, the control volume, and the Navier-Stokes analysis. The magnetization $\mathbf{M}$ is constant in element, and the magnetic field $\mathbf{H}$, the magnetic fluid $\mathbf{v}$, and the concentration ϕ of magnetic particles are on node, as shown in Fig. 2.

FIG. 2 HERE

III. NUMERICAL ANALYSIS FOR MAGNETIC SEPARATION

To investigate the validity of the developed simulation, the simulation results of the magnetic fluid flow with two kinds of the magnetic particles are compared with those of the magnetic fluid flow with one kind of the magnetic particle.

The flow channel of the magnetic chromatography used consists of nano-wires on upper and lower walls, as shown in Fig. 3. The height, width, and length of the flow channel are 0.17 mm, 2.0 mm, and 2.5 mm, respectively. The length is too short to separate the magnetic particles. However, it is shortened to compute the magnetic flow for simplicity. The superconducting magnet applies 2.0 T to the magnetic chromatography. The nano-wires of 0.2 mm width are alternately located on the upper and lower walls of the flow channel inside the magnetic column, which is made of 7% nickel and 93% cobalt. The saturated magnetization of nano-wire is 1.715 T in experiment when the over 0.1 T magnetic field is applied. The body of the magnetic column is made of nonmagnetic stainless steel.

The flowed magnetic particle is the fine Fe_3O_4 particle, its saturation magnetization is 0.9383 T. The initial flow of the entrance of the flow channel is 5.0 mm/s. Table I shows the specifications of the magnetic fluid.

TABLE 1 HERE

A. Simulation of One Kind of Magnetic Particle

First of all, the magnetic fluid flow with two kinds of magnetic particle is individually simulated, their materials are same but their sizes are different, as shown in Table I. The magnetic particle with diameter of 30 nm and the diffusion coefficient of 10^{-2} mm²/s is called the magnetic fluid A, and the magnetic particle with 300 nm diameter and 10^{-3} mm²/s diffusion coefficient the magnetic particle B. Here, the diffusion coefficient is inversely proportional to the size of particle [14]. Fig. 4 shows the concentration of the magnetic particles and the flow in the case of the magnetic fluid A on the vertical cross section at $t = 0.2$ s. Figs. 5 and 6 show the enlarged view of the concentration of the magnetic particles and the flow of the magnetic fluid in the case of the magnetic fluids A and B. Here, the front of the magnetic particles is also shown. The magnetic fluid meanders through the channel by the magnetic forces according to the magnetic gradients on vertical direction in the channel.

B. Simulation of Two Kinds of Magnetic Particle

The magnetic fluid flow simultaneously containing two kinds of magnetic particles are simulated by the developed simulation method. The materials of the magnetic particles are same but the sizes are different (see Table I). Fig. 7 shows the concentrations of the magnetic particles A and B, and the flow of the magnetic fluid on the vertical cross section at $t = 0.2$ s.

The magnetic fluid with particles A and B meanderingly flows also. However, the front of the magnetic particles A and B in Fig. 7 is obviously different from those of the separately simulated magnetic particles A and B in Figs. 5 and 6. The different magnetic force is generated since the composite magnetization is computed considering two kinds of magnetic particles at the same time, derived from (4).

The small differences of the front of the magnetic particles in Figs. 5, 6, and 7 are observed. However, the length of the simulated magnetic column is much shorter than that of the real developed magnetic column [6]. The difference of the velocity of magnetic particles becomes large in experiment.

IV. CONCLUSION

For simulation of a magnetic separation system, it is desired to develop a magnetic fluid simulation tool taking into account magnetism and ferrohydrodynamics. Therefore, we have newly developed the simulation method to consider two or more kinds of the magnetic particles in magnetic fluid for magnetic separation. The proposed simulation method takes into account the magnetic field, the Navier-Stokes, and the control volume analyses in sequence. For consideration of two or more kinds of magnetic particles the composite magnetization is employed and the results of the proposed method are different from the results obtained by the separate simulation.
