Analysis of the Structure and Neuritogenic Activity of Chondroitin Sulfate/Dermatan Sulfate Hybrid Chains from Porcine Fetal Membranes

Taishi Hashiguchi, Shuji Mizumoto, Shuhei Yamada, and Kazuyuki Sugahara

Abstract The amniotic membrane (AM) is the innermost layer of fetal membranes and possesses various biological activities. Although the mechanism underlying these biological activities remains unclear, unique components seem to be involved. AM contains various extracellular matrix components such as type I collagen, laminin, fibronectin, hyaluronic acid, and proteoglycans bearing chondroitin sulfate/dermatan sulfate (CS/DS) glycosaminoglycan side chains. To elucidate the function of CS/DS in AM, the structure and bioactivity of the CS/DS chains from porcine fetal membranes (FM-CS/DS) were investigated. A compositional analysis using various chondroitinases revealed that the characteristic DS domain comprised of iduronic acid-containing disaccharide units is embedded in FM-CS/DS, along with predominant disaccharide units, GlcA-GalNAc, GlcA-GalNAc(4-*O*-sulfate), and GlcA-GalNAc (6-*O*-sulfate), where GlcA and GalNAc represent D-glucuronic acid and *N*-acetyl-D-galactosamine, respectively. The average molecular size of FM-CS/DS chains was unusually large and estimated to be 250 - 300 kDa. The FM-CS/DS chains showed neurite

outgrowth-promoting activity with a dendrite-like morphology, which was eliminated by digestion with chondroitinase ABC of the CS/DS chains. This activity was suppressed by antibodies against growth factors including pleiotrophin, midkine, and fibroblast growth factor-2. The binding of these growth factors to FM-CS/DS was also demonstrated by surface plasmon resonance spectroscopy.

Keywords Chondroitin sulfate, Dermatan sulfate, L-Iduronic acid, Amniotic membrane, Fetal membranes, Neurite outgrowth-promoting activity.

Abbreviations

GAG, glycosaminoglycan; CS, chondroitin sulfate; DS, dermatan sulfate; HS, heparan sulfate; KS, keratan sulfate; HA, hyaluronic acid; AM, amniotic membrane; FM, fetal membranes; IdoA, L-iduronic acid; GlcA, D-glucuronic acid; GalNAc, N-acetyl-D-galactosamine; FGF, fibroblast growth factor-2; PTN, pleiotrophin; MK, midkine; HGF, hepatocyte growth factor; P-ORN, poly-DL-ornithine; HPLC, high performance liquid chromatography; CSase, chondroitinase; NOP, neurite outgrowth-promoting; 2AB, 2-aminobenzamide; Δ HexA, 4-deoxy-L-*threo*-hex-4-enepyranosyluronic acid; IU, international units;

Introduction

Glycosaminoglycans (GAGs) are involved in the regulation of various biological processes such as cell proliferation, differentiation, and migration, cell-cell recognition, extracellular matrix deposition, and tissue morphogenesis [1-4]. GAGs include chondroitin sulfate/dermatan sulfate (CS/DS), heparan sulfate (HS)/heparin, keratan sulfate (KS), and hyaluronic acid (HA). CS/DS chains are found ubiquitously in extracellular matrices and at cell surfaces. The sugar backbone of CS/DS consists of repeating disaccharide units: D-glucuronic acid (GlcA) β /L-iduronic acid (IdoA) α 1-3*N*-acetyl-D-galactosamine (GalNAc). During chain elongation in the biosynthesis of CS/DS, the disaccharide units are modified by specific sulfotransferases at C-2 of GlcA/IdoA, and C-4 and/or C-6 of GalNAc in various combinations, and display enormous structural diversity producing characteristic sulfation patterns critical for the binding to a variety of functional proteins [4]. This structural variability of GAGs is the basis for a wide range of their biological activities.

CS/DS plays crucial roles in various biological events such as the development of the central nervous system [4], wound healing [5, 6], and growth factor signaling [3, 7]. Among these events, the involvement of CS/DS in the development of the central nervous system has attracted attention from a therapeutic point of view for the potential application of CS/DS to nerve regeneration. Several studies have shown that the sulfation pattern of brain CS/DS alters during development, characterized by an increase in 4-*O*-sulfation and a decrease in 6-*O*-sulfation in the whole brain [8], as well

1
2
3 as a dramatic increase in the proportion of IdoA(2-*O*-sulfate)-GalNAc(4-*O*-sulfate)
4
5 units in the cerebellum [9]. The proportion of oversulfated disaccharides and the
6
7 presence of IdoA are crucial factors for the neurite outgrowth-promoting (NOP) activity
8
9 of CS/DS [10-14]. CS/DS chains from embryonic pig brains contain a higher proportion
10
11 of IdoA than those prepared from adult pig brains [12]. They promote the outgrowth of
12
13 neurites of embryonic mouse hippocampal neurons in culture by capturing at least
14
15 endogenous pleiotrophin (PTN) produced by non-neuronal cells (glial cells) and
16
17 hepatocyte growth factor (HGF), and then presenting them to neuronal cells to promote
18
19 neuritogenesis [4, 15, 16].

25
26

27 The amniotic membrane (AM) is the innermost layer of fetal membranes
28
29 (FMs) and possesses various biological activities. Since AM reduces ocular surface
30
31 inflammation and scarring, and promotes rapid epithelialization, it has been applied to
32
33 the treatment of several ocular disorders [17]. The proliferation of corneal epithelial
34
35 cells was promoted when cultivated on human AM [18]. In addition, both mouse and
36
37 human embryonic stem cells efficiently differentiate into neural precursors when
38
39 cultured on human AM matrix components [19]. Although the mechanism underlying
40
41 the biological activities of AM remains unclear, unique components seem to be involved.
42
43 AM contains various extracellular matrix components such as type I collagen, laminin,
44
45 fibronectin, HA, and proteoglycans including CS, HS, and KS chains [20]. Since GAGs
46
47 have been implicated in various biological processes as described above, we
48
49 hypothesized that GAGs in AM may play a major role in the biological activities of AM.

1
2
3 Notably, CS/DS in AM may be involved in the induction of the differentiation of
4
5 embryonic stem cells into neuronal precursors. Hence, in this study GAGs were isolated
6
7 from porcine FMs containing amnions, and their structure and NOP activity were
8
9 analyzed.

17 **Materials and methods**

18
19 *Materials* The following sugars and enzymes were purchased from Seikagaku Corp.
20
21 (Tokyo, Japan): CS-E from squid cartilage, standard unsaturated disaccharides,
22
23 chondroitinase (CSase) ABC (EC 4.2.2.4) from *Proteus vulgaris*, CSase AC-I (EC
24
25 4.2.2.5) from *Flavobacterium heparinum*, CSase AC-II (EC 4.2.2.5) from *Arthrobacter*
26
27 *aureus*, keratanase II (EC 3.2.1.) from *Bacillus sp.*, and hyaluronidase (EC 4.2.2.1)
28
29 from *Streptomyces hyalurolyticus*. CSase B (EC 4.2.2.19), and heparinases (Hepases) I
30
31 (EC 4.2.2.7) and III (EC 4.2.2.8) from *Flavobacterium heparinum* were purchased from
32
33 IBEX Technologies (Montreal, Canada). Porcine FMs were obtained from Hokudo Corp.
34
35 (Hokkaido, Japan). Pregnant ddY mice were purchased from SLC Inc. (Shizuoka,
36
37 Japan). Poly-DL-ornithine (P-ORN), anti-neurofilament and anti-HGF-antibodies, and
38
39 serum immunoglobulins from mouse and goat, were purchased from Sigma. Actinase E
40
41 was obtained from Kaken Pharmaceutical Co. (Tokyo, Japan).
42
43 Anti-microtubule-associated protein 2 was purchased from Leico Technologies Inc. (St.
44
45 Louis, MO). Recombinant human (rh)-PTN, rh-fibroblast growth factor-2 (FGF-2), and
46
47 rh-HGF were purchased from Wako Corp. (Osaka, Japan). Anti-FGF-2 was from

Upstate Biotechnology, Inc. (New York, NY). Anti-PTN and anti-midkine (MK) antibodies, and rh-MK were purchased from R&D Systems (Minneapolis, MN). Accell Plus QMA anion-exchange cartridges were obtained from Waters Corp. Dialysis membranes were purchased from Spectrum laboratories Corp. (Rancho Dominguez, CA).

Extraction of the GAG-peptide fraction from porcine FMs Porcine FMs (350 g in wet weight) were cut into pieces with scissors, boiled in 650 ml of water for 10 min to inactivate proteases and glycosidases, cooled, and digested with 3 g of actinase E in a total volume of 900 ml of 0.1 M borate-sodium buffer, pH 8.0, containing 10 mM calcium chloride as described previously [21]. The digestion was carried out at 60 °C for 96 h, and an additional 1.5 g each of the enzyme was added after 24, 48, and 72 h. Following incubation, the sample was precipitated with 5% trichloroacetic acid and centrifuged. The supernatant was treated with diethylether to remove trichloroacetic acid. The aqueous phase was neutralized using 1 M sodium carbonate, and treated with 80% ethanol containing 1% sodium acetate at 4 °C overnight. The resultant precipitate was reconstituted in 160 ml of water, and subjected to anion-exchange chromatography on an Accell QMA Plus cartridge (Waters, Milford, MA), which was eluted stepwise with 50 mM phosphate buffers, pH 6.0, containing 0.15, 1.0, and 2.0 M NaCl [21]. Each eluted fraction was desalted using a Spectra/Por dialysis membrane (Spectrum laboratories Corp., Rancho Dominguez, CA). Uronic acid in each fraction was

quantified by the carbazole method [22].

Purification of FM-CS/DS The fractions, which were eluted with buffers containing 1.0 and 2.0 M NaCl from an Accell QMA Plus cartridge, presumably contained GAG-peptides from FMs, and were digested with hyaluronidase from *Streptomyces hyalurolyticus* to eliminate HA as described previously [13]. The resultant HA fragments were removed by Centricon YM-10 (cut off molecular weight: 10,000) (Millipore, Bedford, MA). The 1.0 and 2.0 M NaCl-eluted fractions were then subjected to nitrous acid treatment to eliminate HS as reported previously [13], and the resultant HS fragments were removed by Centricon YM-10. The 1.0 and 2.0 M NaCl-eluted fractions were then digested with keratanase II in a 10 mM sodium acetate buffer, pH 6.5, at 37 °C for 1 h, and the resultant KS fragments were removed by Centricon YM-10. Finally, the purified fractions were treated with 1.0 M NaBH₄/0.5 M NaOH at room temperature for 2 h to liberate peptides from GAG polysaccharides. The samples were acidified with acetic acid to decompose excess NaBH₄, neutralized with 1 M sodium carbonate, and passed through a Sep-PakC₁₈ (Waters) cartridge to remove peptide fragments. The purified 1.0 and 2.0 M NaCl-eluted FM-CS/DS fractions were used for the structural and functional analyses.

Enzymatic digestion The GAG-peptide fractions from FMs, which were eluted using 1.0 and 2.0 M NaCl from an Accell QMA Plus cartridge, were digested with a mixture of

1
2
3 CSases ABC and AC-II, CSase B, a mixture of CSases AC-I and AC-II [13], or a
4
5 mixture of Hepases I and III [23]. Unsaturated di- and oligosaccharides produced were
6
7 derivatized with 2-aminobenzamide (2AB), and then analyzed by anion-exchange
8
9 HPLC on an amine-bound silica PA-03 column (YMC Co., Kyoto, Japan) [24]. The
10
11 GAG-peptide fractions from FMs were also digested with keratanase II as described
12
13 above. The digests were derivatized with 2AB, and then analyzed by anion-exchange
14
15 HPLC on an amine-bound silica PA-03 column [24].
16
17
18
19
20
21
22
23

24 *Gel-filtration chromatography of the FM-CS/DS preparations* The FM-CS/DS
25
26 preparations (20 µg each as CS/DS) were subjected to gel-filtration chromatography on
27
28 a column of Sephacryl S-400 HR16/60 (GE healthcare, Uppsala, Sweden) using 0.2
29
30 M ammonium acetate as an effluent with a flow rate of 0.4 ml/min. Fractions were
31
32 collected at 1min intervals, lyophilized, and digested with CSase ABC. The digests were
33
34 derivatized with 2AB, and then analyzed by HPLC on an amine-bound silica column
35
36 [24].
37
38
39
40
41

43
44
45

46 *Analysis of the distribution of IdoA residues in the FM-CS/DS preparations* The 1.0 and
47
48 2.0 M NaCl-eluted FM-CS/DS preparations (1 µg each as GAG) were digested with
49
50 CSase AC-I. Each digest was labeled with 2AB, and analyzed by gel-filtration HPLC on
51
52 a column (10 X 300 mm) of SuperdexTM Peptide HR10/330 (Amersham Biosciences,
53
54 Uppsala, Sweden), which was eluted with 0.2 M ammonium bicarbonate at a flow rate
55
56
57
58
59
60
61
62
63
64
65

1
2
3 of 0.4 ml/min. The percentage of galactosaminidic bonds cleaved by CSase AC-I was
4
5
6 calculated based on the fluorescent intensity across peaks relative to the total amount of
7
8
9 the disaccharides generated by digestion with CSase ABC [12]. The molar ratio of IdoA
10
11 to GlcA (IdoA/GlcA) was calculated based on the peak area as follows: (the amount of
12
13 total disaccharides released by CSase ABC minus the amount of oligo- and
14
15 disaccharides released by CSase AC-I)/(the amount of oligo- and disaccharides released
16
17 by CSase AC-I).
18
19
20
21
22
23

24
25 *Assays for NOP activity* Cultures of hippocampal cells were established from E16 mice
26
27 as previously described [11, 25]. Briefly, 2 µg/well of a FM-CS/DS preparation was
28
29 coated onto coverslips precoated with P-ORN at 4 °C overnight. The hippocampal cells
30
31 were freshly isolated from E16 mouse embryos, suspended in Eagle's minimum
32
33 essential medium containing N2 supplements [26], seeded on coverslips at a density of
34
35
36 20,000 cells/cm², and allowed to grow in a humidified atmosphere for 24 h at 37 °C
37
38
39 with 5 % CO₂.
40
41
42

43
44 For the inhibition assay using antibodies, polyclonal anti-PTN (10 µg/ml),
45
46 anti-MK (10 µg/ml), anti-FGF-2 (10 µg/ml), or anti-HGF (10 µg/ml) antibodies were
47
48 added to the medium, 2 h after the seeding of the hippocampal cells. After incubation
49
50
51 overnight, the cells were fixed using 4% (w/v) paraformaldehyde for 1 h at room
52
53
54 temperature, and the neurites were visualized by immunochemical staining using
55
56
57 anti-microtubule associated protein 2 (Lieco Technomogies Inc., St. Louis, MO) and
58
59
60
61
62
63
64
65

1 anti-neurofilament (Sigma) antibodies as described [11]. The antibodies were then
2
3 detected using a Vectastain ABC kit (Vector Laboratories Inc., Burlingame, CA) with
4
5 3,3'-diaminobenzidine as a chromogen. NOP activity was evaluated by determining the
6
7 length of the longest neurite and the number of primary neurites of 100 randomly
8
9 selected neurons using FLVFS-LS software (Olympus, Tokyo, Japan).

13
14
15
16
17
18
19 *Surface plasmon resonance analysis* The interaction of various growth/neurotrophic
20
21 factors with the FM-CS/DS preparations was examined using a BIAcore X system
22
23 (BIAcore AB, Uppsala, Sweden) as reported [12]. For the kinetic analysis, various
24
25 concentrations of each growth/neurotrophic factor were injected onto the surface of the
26
27 FM-CS/DS-immobilized sensor chip in the running buffer, pH 7.4 (HBS-EP, BIAcore
28
29 AB), containing 10 mM HEPES, 0.15 M NaCl, 3 mM EDTA, and 0.005% (w/v) Tween
30
31 20 at a flow rate of 30 μ l/min [12]. Before each injection, base-line stabilization was
32
33 achieved by injecting 1.0 M NaCl for 2 min. The kinetic parameters were evaluated
34
35 with BIAevaluation software 4.1 (BIAcore AB) using a 1:1 binding model with mass
36
37 transfer, and the association and dissociation rate constants (k_a and k_d) as well as the
38
39 dissociation equilibrium constants (K_d) were determined.

51 **Results**

52
53
54 *Characterization of GAGs in porcine FMs* To characterize GAGs in porcine FMs, a
55
56 GAG-peptide fraction was prepared by digestion with actinase E, followed by
57
58
59
60
61
62
63
64
65

1
2
3 trichloroacetic acid treatment and ethanol precipitation. This GAG-peptide fraction was
4
5 further fractionated by anion-exchange chromatography using an AccellTM Plus QMA
6
7 cartridge, which was eluted stepwise with buffers containing 0.15, 1.0, and 2.0 M NaCl.
8
9 Only trace amounts of GAGs were detected in the fraction eluted with the buffer
10
11 containing 0.15 M NaCl. The fractions eluted with 1.0 and 2.0 M NaCl were digested
12
13 with a mixture of CSases ABC and AC-II, a mixture of Hepases I and III, or keratanse II.
14
15 The digests were labeled with a fluorophore 2AB and analyzed by anion-exchange
16
17 HPLC, and the GAG disaccharide composition in each fraction was quantified based on
18
19 the fluorescent intensity of the derivatives (Table 1).
20
21
22
23
24
25
26

27 Representative chromatograms for the CS/DS disaccharide analysis are shown
28
29 in Fig. 1, and the data are summarized in Table 2. The FM-CS/DS chains in the 1.0 M
30
31 NaCl-eluted fraction were low sulfated as evidenced by a significant proportion of
32
33 nonsulfated disaccharide unit, Δ HexA-GalNAc (40.5%), with a sulfate/disaccharide unit
34
35 ratio of 0.6, whereas the FM-CS/DS chains in the 2.0 M NaCl-eluted fraction were
36
37 enriched with monosulfated disaccharide units, Δ HexA-GalNAc(4-*O*-sulfate) (61.0%),
38
39 and Δ HexA-GalNAc(6-*O*-sulfate) (27.6%), with a sulfate/disaccharide unit ratio of 0.9
40
41 (Table 2).
42
43
44
45
46
47
48

49 To examine whether the FM-GAG fractions contain DS, an anion-exchange
50
51 HPLC analysis was carried out after digestion with a mixture of CSases AC-I and AC-II
52
53 or CSase B alone, which specifically cleaves the *N*-acetylgalactosaminidic linkages
54
55 flanked by GlcA or IdoA residues, respectively (Fig. 1 and Table 2). The GAG-peptide
56
57
58
59
60
61
62
63
64
65

fractions were sensitive to the action of both types of enzymes, suggesting that the CS/DS chains have a hybrid structure.

Disaccharides derived from HA were also detected in the digest with a mixture of CSases ABC and AC-II. The total amounts of HA disaccharides produced by digestion of the 1.0 and 2.0 M NaCl-eluted GAG-peptide fractions with CSases were 1,085 and 104 pmol per mg of porcine FM (wet weight), respectively (Table 1). The GAG-peptide fractions were also subjected to a compositional analysis of HS disaccharides after digestion with a mixture of Hepases I and III. The total amounts of HS disaccharides produced were only 57 and 2 pmol per mg of porcine FM (wet weight), respectively. When the digest of the GAG-peptide fractions with keratanase II was analyzed by anion-exchange HPLC, KS disaccharides were detected only in the 2.0 M NaCl-eluted GAG-peptide fraction and the amount was 11 pmol per mg of porcine FM (wet weight).

The molecular size of CS/DS chains in the 1.0 and 2.0 M NaCl-eluted fractions was analyzed by gel-filtration chromatography. An aliquot of each eluate was subjected to digestion with CSase ABC and the digests were labeled with 2AB and analyzed by anion-exchange HPLC. The amount of the 2AB-derivatives of unsaturated CS/DS disaccharides was calculated based on fluorescent intensity. Using a calibration plot generated with data obtained with polysaccharides of known sizes (Fig. 2, *inset*), the average molecular size of the major CS/DS chains in the 1.0 and 2.0 M NaCl-eluted fractions was estimated to be 301 and 249 kDa, respectively (Fig. 2).

To further characterize the structural properties of the IdoA-containing FM-CS/DS preparations, the distribution of IdoA residues along the chains was compared between the 1.0 and 2.0 M FM-CS/DS preparations. Each FM-CS/DS preparation was treated with CSase AC-I, and each digest was labeled with 2AB and analyzed by gel-filtration HPLC on a column of Superdex peptide. As shown in Fig. 3, fluorescent peaks derived from each digest were detected at the elution of positions corresponding to hexa- and tetrasaccharides, in addition to di-, mono-, and nonsulfated disaccharides. Considering the substrate specificity of CSase AC-I (27), the oligosaccharide resistant to CSase AC-I is most likely derived from the sequences containing IdoA residues. Upon digestion of the 1.0 M NaCl-eluted FM-CS/DS fraction, disaccharides were predominantly detected as shown in Fig. 3A. On the other hand, the digestion of the 2.0 M NaCl-eluted FM-CS/DS fraction with CSase AC-I gave oligosaccharides ranging in size from disaccharides to polysaccharides (Fig. 3B). The oligosaccharides in the digest obtained with CSase AC-I are composed of contiguous IdoA-containing disaccharide units. The molar ratio of IdoA to GlcA plus IdoA was calculated based on the peak area, and in the 1.0 and 2.0 M NaCl-eluted FM-CS/DS fractions was 0.23 and 0.62, respectively. These results suggest that the proportion of the characteristic DS domain constituted of IdoA-containing disaccharide units is approximately 3 times higher in the 2.0 M than 1.0 M NaCl-eluted FM-CS/DS fraction.

NOP activity of the FM-CS/DS preparations To evaluate the biological activity of the

1
2
3 CS/DS chains in FM, they were purified from the GAG-peptide fractions of porcine FM.
4
5 HA, HS and KS were removed from the GAG-peptide fractions by digestion with
6
7 hyaluronidase, treatment with nitrous acid, and digestion with keratanase II, respectively.
8
9 The purified fractions were treated with 1.0 M NaBH₄/0.5 M NaOH at room
10
11 temperature for 2 h to liberate CS/DS chains from the core peptides, and the products
12
13 were passed through a Sep-PakC₁₈ cartridge to remove peptide fragments.
14
15
16
17
18

19 The purified 1.0 and 2.0 M NaCl-eluted FM-CS/DS fractions were assessed
20
21 for NOP activity. Mouse E16 hippocampal cells were cultured on plastic coverslips
22
23 coated with P-ORN and then with the 1.0 or 2.0 M NaCl-eluted FM-CS/DS fraction
24
25 (Figs. 4A and 4B) or CS-E (Fig. 4C) as a positive control. After incubation for 24 h, the
26
27 cells were fixed and immunostained with anti-microtubule-associated protein 2 and
28
29 anti-neurofilament antibodies. In the negative control experiment, cells were cultured on
30
31 coverslips coated with P-ORN alone (Fig. 4D). The mean length of the longest neurite
32
33 and the number of primary neurites per cell of 100 randomly selected neurons cultured
34
35 on various substrates were measured.
36
37
38
39
40
41
42

43 The mean length of the longest neurites was significantly greater for the
44
45 neurons cultured on the FM-CS/DS preparations than for the cells cultured on
46
47 coverslips coated with P-ORN alone (Fig. 5). The number of primary neurites was also
48
49 larger for the neurons cultured on the FM-CS/DS preparations than those cultured on
50
51 P-ORN alone (Fig. 5). Although only a single long neurite per neuron was usually
52
53 observed for neurons cultured on P-ORN alone, neurons grown on the plates coated
54
55
56

19 Although both the FM-CS/DS preparations and CS-E displayed marked NOP
20
21 effects (Fig. 4), the morphology of the neurons cultured on these substrates was
22
23 different. The neurons cultured on the CS-E-coated substrate exhibited a round-shaped
24
25 morphology (Fig. 4C), being consistent with previous observations [11]. On the other
26
27 hand, the neurons cultured on the FM-CS/DS preparations extended multiple neurites
28
29 and showed a flattened dendrite-like morphology (Figs. 4A and B) as observed for the
30
31 neurons cultured on a CS-D-coated substrate [25].
32
33
34
35
36
37

38 CS/DS specifically interacts with PTN, MK, FGF-2, and HGF, which have
39
40 neurotrophic activity and are widely expressed as autocrine and paracrine pleiotropic
41
42 factors in distinct neuronal cell populations of the developing and adult brain, including
43
44 hippocampal neuronal cells [28-30]. Hence, these endogenous heparin-binding growth
45
46 factors may be involved in the mechanism of the NOP activity of FM-CS/DS. To verify
47
48 this possibility, antibodies against HGF, PTN, MK, and FGF-2 were individually added
49
50 and it was examined whether the NOP activity of FM-CS/DS chains toward
51
52 hippocampal neurons was neutralized. The addition of anti-MK antibody markedly
53
54
55
56
57

1
2
3 suppressed the NOP activity of 1.0 M NaCl-eluted FM-CS/DS chains to the background
4
5 level of P-ORN, suggesting that the NOP activity of the 1.0 M NaCl-eluted FM-CS/DS
6
7 chains is expressed mainly through the signaling pathway of MK (Fig. 6A). On the
8
9 other hand, the NOP activity of the 2.0 M NaCl-eluted FM-CS/DS chains was
10
11 suppressed by the antibodies against PTN and FGF-2 by 54 and 51%, respectively,
12
13 suggesting the involvement of the signaling pathways of PTN and FGF-2 in the
14
15 expression of the NOP activity of the 2.0 M NaCl-eluted FM-CS/DS chains.

21
22
23
24

25 *Kinetic analysis of the binding of growth factors to FM-CS/DS* The NOP activity of the
26
27 FM-CS/DS chains was suppressed by the antibodies against PTN, MK, and FGF-2 (Fig.
28
29 6). Since CS/DS chains have been demonstrated to act as co-receptors for various
30
31 growth factors [7], interactions with these heparin-binding growth factors may be
32
33 involved in the promotion of neurite outgrowth by the FM-CS/DS chains. To examine
34
35 this possibility, a kinetic analysis of the binding of these growth factors to immobilized
36
37 FM-CS/DS chains was carried out using the BIAcore system. The FM-CS/DS
38
39 preparations were biotinylated and immobilized on the streptavidin-precoated sensor
40
41 chip. The heparin-binding growth factors (PTN, MK, FGF-2, and HGF) were injected at
42
43 different concentrations individually onto the surface of the sensor chip. Overlaid
44
45 sensorgrams are shown in Fig. 7. These sensorgrams were analyzed with BIAevaluation
46
47 4.1 software using the "1:1 binding model with mass transfer" to calculate the kinetic
48
49 parameters (Table 3).

Although MK and FGF-2 bound to the 1.0 M NaCl-eluted FM-CS/DS chains, PTN and HGF did not (data not shown). MK displayed quick binding and slow dissociation, giving a K_d value of 27.1 nM and signifying their strong affinity for the 1.0 M NaCl-eluted FM-CS/DS chains. On the other hand, all the growth factors tested bound to the 2.0 M NaCl-eluted FM-CS/DS chains. PTN and MK showed high affinity, displaying K_d values of 463.4 and 53.3 nM, respectively. The kinetic parameters for the binding of FGF-2 and HGF are not shown in Table 3, because good fitting models were not obtained for their sensorgrams (data not shown). However, the data on the binding of FGF-2 and HGF to the FM-CS/DS chains can be used qualitatively.

Discussion

In this study, to elucidate the biological activities of CS/DS chains in AM, the structure and bioactivity of FM-CS/DS chains were investigated. The disaccharide compositional analysis showed that the major components of the FM-CS/DS chains are GlcA-GalNAc, GlcA-GalNAc(4-*O*-sulfate), and GlcA-GalNAc(6-*O*-sulfate) disaccharide units, and that IdoA-containing disaccharide units are clustered in the polysaccharide chains. Because of the flexibility of its sugar ring, IdoA shows a conformational diversity [31, 32], which may provide IdoA-containing GAGs with a range of finely tuned affinities for different bioactive proteins [33]. DS, which mainly consists of IdoA-GalNAc(4-*O*-sulfate) disaccharide units, promotes the binding of FGF-7 to a FGF receptor and the cell proliferation of keratinocytes [6], and also acts as a co-receptor

1
2
3 required for the formation of an active HGF signaling complex [34, 35]. The DS-like
4
5 structure in *Xenopus* CS/DS was reported to be involved in its binding to FGF-1 [36].
6
7
8 The unusually flexible ring conformation of IdoA residues in FM-CS/DS may be
9
10 involved in the biological activities of AM such as promotion of the proliferation of
11
12 corneal epithelium [18] and regeneration of esophagus and skin [37, 38] mediated by
13
14 growth factors' signaling.
15
16
17
18

19 Based on the analysis of the molecular sizes of the 1.0 and 2.0 M NaCl-eluted
20
21 FM-CS/DS preparations, the average molecular sizes of the 1.0 and 2.0 M NaCl-eluted
22
23 FM-CS/DS chains were estimated to be 301 and 249 kDa, respectively. These chains are
24
25 linear polymers consisting of approximately 500 - 600 repeating disaccharide units and
26
27 unusually larger than the CS/DS chains from other sources including embryonic pig
28
29 brain (40 kDa) [12], shark skin (70 kDa) [13], shark liver (76 kDa) [16], and hagfish
30
31 notochord (18 kDa) [14]. The markedly large CS chains (350 kDa) attach to type IX
32
33 collagen in the chick embryo vitreous humor [39], which are presumed to distribute in a
34
35 regular periodic arrangement along the collagen fibrils. AM has been utilized for the
36
37 treatment of several corneal diseases such as corneal opacity and damaged corneas [18].
38
39 Since normal cornea abundantly contains collagen fibrils, the markedly large size of
40
41 FM-CS/DS may contribute to the treatment of corneal diseases.
42
43
44
45
46
47
48
49
50
51

52 The NOP activity of the FM-CS/DS preparations was analyzed in this study to
53
54 investigate potential applications to nerve regeneration. The 1.0 M NaCl-eluted
55
56 FM-CS/DS exhibited NOP activity with a dendrite-like morphology, and this activity
57
58
59
60
61
62
63
64
65

1
2
3 was completely inhibited by the antibody against a neurotrophic factor MK, which
4
5 showed a strong affinity for the 1.0 M NaCl-eluted FM-CS/DS chains displaying a K_d
6
7 value of 53.3 nM. Several studies have demonstrated that endogenous
8
9 growth/neurotrophic factors such as PTN, HGF, MK, and brain-derived neurotrophic
10
11 factor are recruited by CS/DS chains and then presented to neuronal cells to promote
12
13 neuritogenesis [4, 15, 16, 40]. These findings suggest that endogenous MK appears to
14
15 be recruited by the 1.0 M NaCl-eluted FM-CS/DS chains and involved in the induction
16
17 of the NOP activity. MK is a heparin-binding neurotrophic factor that promotes the
18
19 growth, survival, and migration of various cells [41]. A cluster of
20
21 GlcA-GalNAc(4,6-*O*-disulfate) units in CS-E from squid cartilage exhibits strong
22
23 binding to MK ($K_d = 62$) [42, 43]. However, the FM-CS/DS chains contain little
24
25 GlcA-GalNAc(4,6-*O*-disulfate) unit (0.03 %), indicating that the functional domains in
26
27 the 1.0 M NaCl-eluted FM-CS/DS chains for the MK-binding do not appear to contain
28
29 GlcA-GalNAc(4S,6S) units, but rather a cluster of IdoA-containing disaccharides,
30
31 which interacts with MK [12] and influences the biological activity of MK, may be
32
33 involved [44].
34
35
36
37
38
39
40
41
42
43
44
45

46 The 2.0 M NaCl-eluted FM-CS/DS preparation also displayed marked NOP
47
48 activity with a dendrite-like morphology, and its activity level was significantly higher
49
50 than that of the 1.0 M NaCl-eluted FM-CS/DS chains. A contribution of
51
52 IdoA-containing disaccharide units to the neuritogenic activity of CS/DS chains has
53
54 been demonstrated using CS/DS preparations derived from embryonic pig brain [12],
55
56
57
58
59
60
61
62
63
64
65

1 shark skin [13], and hagfish notochord [14]. Consecutive IdoA residues appear to be
2
3
4
5
6 essential for the NOP activity of the FM-CS/DS chains, being consistent with the
7
8
9 observation that the 2.0 M NaCl-eluted FM-CS/DS chains contain a higher proportion
10
11 of IdoA-containing disaccharide units than the 1.0 M NaCl-eluted FM-CS/DS chains.
12
13 The NOP activity of the 2.0 M NaCl-eluted FM-CS/DS chains was diminished by the
14
15
16 antibodies against PTN and FGF-2 by 54 and 51%, respectively, suggesting the
17
18 involvement of the signaling pathways of PTN and FGF-2 in the expression of the NOP
19
20 activity of the 2.0 M NaCl-eluted FM-CS/DS chains. However, the NOP activity of the
21
22
23 2.0 M NaCl-eluted FM-CS/DS chains was not completely eliminated by the addition of
24
25
26 the mixture of these antibodies (data not shown). Recently, Mikami *et al.* reported that
27
28 CS-E can act as an effective ligand for the neuronal cell surface receptor contactin-1
29
30 that stimulates the intracellular signaling pathway involved in neuritogenesis [45]. Cell
31
32 adhesion molecules such as contactin-1 may be involved in the induction of the NOP
33
34 activity of the 2.0 M NaCl-eluted FM-CS/DS chains to some extent.
35
36
37
38
39
40

41 The matrix components of human AM can convert embryonic stem cells into
42
43 neural tissues selectively [19]. Since CS/DS is a major component of the extracellular
44
45 matrix, the NOP activity of the FM-CS/DS chains demonstrated in this study may be
46
47 involved in the neurogenerative activity of AM. AM has also been applied to several
48
49 ocular disorders, because it can promote epithelialization, inhibit fibrosis, and reduce
50
51 ocular surface inflammation [17]. In addition, it has antimicrobial and antiviral
52
53 properties and high hydraulic conductivity [17]. Basement membrane components in
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3 AM can improve the morphogenesis of epidermis and basement membranes in
4
5 constructing a human living skin-equivalent [38]. The *in situ* tissue-engineered
6
7 esophagus, which is prepared by cultivating oral keratinocytes and fibroblasts on human
8
9 AM, can successfully replace the intrathoracic esophagus [37]. Since CS/DS is involved
10
11 in biological events such as cell proliferation [3, 6], viral infection [46], inflammation
12
13 [47], anti-coagulation [33], and wound healing [5, 6, 48], it may contribute to some of
14
15 the biological activities of AM described above. The information obtained in this study
16
17 facilitates deeper understanding of the biological activities of AM, and suggests
18
19 potential applications of FM-CS/DS chains.

Figure legends

Fig. 1 Anion-exchange HPLC of CSase digests of the 2.0 M NaCl-eluted FM-CS/DS fraction. The 2.0 M NaCl-eluted FM-CS/DS fraction was digested with a mixture of CSases ABC and AC-II (A), a mixture of CSases AC-I and AC-II (B), or CSase B (C). Each digest was labeled with 2AB, and analyzed by anion-exchange HPLC on an amine-bound silica PA-03 column using a linear NaH_2PO_4 gradient (indicated by the *dashed line*). The elution positions of authentic 2AB-labeled unsaturated disaccharides are indicated by *bars*. 1, $\Delta\text{HexA-GlcNAc}$; 2, $\Delta\text{HexA-GalNAc}$; 3, $\Delta\text{HexA-GalNAc(6-O-sulfate)}$; 4, $\Delta\text{HexA-GalNAc(4-O-sulfate)}$; 5, $\Delta\text{HexA(2-O-sulfate)-GalNAc(6-O-sulfate)}$; 6, $\Delta\text{HexA(2-O-sulfate)-GalNAc(4-O-sulfate)}$; 7, $\Delta\text{HexA-GalNAc(4,6-O-disulfate)}$. The peaks marked by *asterisks* are derived from the 2AB-labeling reagents. The insets in (A) and (C) show enlarged views (100-fold and 20-fold, respectively).

Fig. 2 Determination of the molecular size of the FM-CS/DS chains by gel-filtration chromatography. The FM-CS/DS preparations eluted with buffers containing 1.0 or 2.0 M NaCl (20 μg of each as GAG) were fractionated on a column of Sephacryl S-400 using 0.2 M ammonium acetate as an effluent with a flow rate of 1 ml/min. Fractions were collected at 2 min intervals. Each fraction was subjected to digestion with CSase ABC and labeled with 2AB. The 2AB-labeled digest was analyzed by anion-exchange HPLC on an amine-bound silica PA-03 column. The amount of the 2AB-derivatives of

1
2
3 unsaturated CS/DS disaccharides was calculated based on fluorescent intensity. The

Table 1 Analysis of GAG composition of the fractions isolated from the FM-GAG fraction^a

	1.0 M NaCl-eluted FM-GAG fraction	2.0 M NaCl-eluted FM-GAG fraction
	pmol as disaccharides/mg tissue	
CS/DS	684 (37.5) ^b	149 (56.0)
HA	1,085 (59.4)	104 (39.1)
KS	ND ^c	11 (4.1)
HS	57 (3.1)	2 (0.8)
Total GAG	1,826 (100)	266 (100)

^aFM-GAG fractions were digested with a mixture of CSases ABC and AC-II, a mixture of Hepases I and III, or keratanase II. Each digest was analyzed by anion-exchange HPLC after 2AB-derivatization, and the GAG composition of each fraction was quantified based on the fluorescent intensity of the derivatives (see "Materials and methods").

^bThe values in parentheses give the proportions of the respective GAGs.

^cND, not detected.

Table 2 Disaccharide composition of the FM-CS/DS preparations^a

CS/DS disaccharides	1.0 M NaCl-eluted FM-CS/DS			2.0 M NaCl-eluted FM-CS/DS		
	CSases ABC and AC-II	CSases AC-I and AC-II	CSase B	CSases ABC and AC-II	CSases AC-I and AC-II	CSase B
	pmol as disaccharides/mg tissue			pmol as disaccharides/mg tissue		
ΔHexA-GalNAc	277.1 (40.5) ^b	250.6 (45.9)	ND	14.8 (9.9)	12.2 (16.9)	ND
ΔHexA-GalNAc(6S)	178.9 (26.2)	166.1 (30.3)	ND	41.1 (27.6)	35.1 (48.2)	ND
ΔHexA-GalNAc(4S)	223.5 (32.7)	130.3 (23.8)	17.3 (97.4)	90.9 (60.9)	25.3 (34.8)	12.2 (94.8)
ΔHexA(2S)-GalNAc(6S)	2.6 (0.4)	ND ^c	ND	0.7 (0.5)	ND	ND
ΔHexA(2S)-GalNAc(4S)	1.4 (0.2)	ND	0.5 (2.6)	1.4 (0.9)	ND	0.7 (5.2)
ΔHexA-GalNAc(4S,6S)	0.2 (0.03)	ND	ND	0.2 (0.2)	0.1 (0.1)	ND
Total	683.7 (100)	546.9 (100)	17.7 (100)	149.1 (100)	72.7 (100)	12.9 (100)
S/unit ^d	0.6	0.5	1	0.9	0.8	1.1

^aFM-CS/DS preparations were digested with a mixture of CSases ABC and AC-II, a mixture of CSases AC-I and AC-II, or CSase B, and individually analyzed by anion-exchange HPLC after 2AB-labeling (see "Materials and methods").

^bThe values in parentheses give the molar proportions of the respective disaccharides.

^cND, not detected

^dS/unit, the number of sulfate groups per disaccharide unit.

Table 3 Kinetic parameters for the interactions of neurotrophic factors with immobilized FM-CS/DS preparations^a

Neurotrophic factors	1.0 M NaCl-eluted FM-CS/DS			2.0 M NaCl-eluted FM-CS/DS		
	k_a	k_d	K_d	k_a	k_d	K_d
	$M^1 s^{-1}$	s^{-1}	nM	$M^1 s^{-1}$	s^{-1}	nM
PTN	- ^b	-	-	$(1.9 \pm 0.8) \times 10^4$	$(8.5 \pm 4.2) \times 10^{-3}$	463.4 ± 245.1
MK	$(2.1 \pm 0.8) \times 10^6$	$(3.8 \pm 2.7) \times 10^{-2}$	27.1 ± 1.0	$(1.2 \pm 0.5) \times 10^6$	$(6.0 \pm 2.4) \times 10^{-2}$	53.3 ± 16.1

^a The k_a , k_d , and K_d values were determined using a 1:1 binding model with mass transfer as described under "Materials and methods".

The values for each neurotrophic factor are expressed as the mean $\pm$ S.E. obtained with five different concentrations.

^b-, no significant interaction with the 1.0 M NaCl-eluted FM-CS/DS preparation.
