## ABSTRACT

**Fra-2, one of the Fos-related antigens, is promptly expressed after the growth stimulation of fibroblasts, but its induction peak is later than that of c-Fos. In this report, we examined biochemical properties of Fra-2 and compared them with those of two other Fos family proteins, c-Fos and Fra-1. Like c-Fos and Fra-1, Fra-2 formed stable heterodimers with c-Jun, JunB or JunD *in vitro* and all these complexes had specific DNA-binding activity to AP-1-binding sites (AP-1 sites) or related sequences. When transiently introduced into a mouse embryonic carcinoma cell line, F9, with reporter genes containing the AP-1 site from the collagenase gene, *fra-2* plus *c-jun* suppressed the transactivation by *c-jun* alone. This property of Fra-2 is in clear contrast to that of c-Fos, which stimulates the transcriptional activity of c-Jun by forming a stable heterodimer. Analysis of chimeric proteins between c-Fos and Fra-2 indicated that this difference is mainly attributable to their C terminal-half regions. Interestingly, this suppressive effect of Fra-2 was not observed in the combination with JunD: *fra-2* plus *junD*, like *c-fos* plus *junD*, had higher transcriptional activity than *junD* alone. Fra-1 showed essentially the same transcriptional regulatory properties as Fra-2. These differential properties greatly expand the potential range of regulatory functions of the Fos family proteins.**

## INTRODUCTION

A growing body of evidence indicates that protooncogenes *c-fos* and *c-jun* play important roles in cellular growth and differentiation. The protein products of *c-fos* and *c-jun* (c-Fos and c-Jun, respectively) function cooperatively as transcriptional regulators in a heterodimeric complex (1–5). c-Jun, unlike c-Fos, also forms homodimers, although these are less stable than Fos/Jun heterodimers. The dimeric complexes interact with activator protein-1 (AP-1)-binding sites (TGACTCA) to regulate

transcription (6–10). Dimerization of Fos and Jun is mediated by the leucine zipper structure (11). Dimer formation results in the juxtaposition of conserved basic regions of each protein that form a bipartite DNA binding domain (12, 13).

To date, several related genes of these protooncogenes have been reported; *fra-1* (14, 15), *fosB* (16) and *fra-2* (17–19) as *fos*-related genes and *junB* (20) and *junD* (21,22) as *jun*-related genes. Among the same family, the gene products share common biological functions; however, they are also expected to have distinct functions as was shown by comparative studies between c-Jun and JunB (23, 24).

Fra-2 was initially detected as a serum-inducible Fos-related antigen (17). The induction peak of this immediate-early gene product is later than that of c-Fos. Unlike c-Fos, Fra-2 is synthesized at a low level even in growth-arrested chicken embryo fibroblasts (CEF) or logarithmically growing CEF (17, 19). We have molecularly cloned the gene from chicken genomic library. Overexpression of *fra-2* gene, like *c-fos* gene (25, 26), caused cellular transformation of CEF (17). Although Fra-2 was shown to form a complex with c-Jun *in vivo*, its biochemical properties are poorly known.

In this study, we firstly cloned *fra-2* cDNA and demonstrated its biochemical properties *in vitro*, such as dimer-forming activity with Jun family proteins and specific DNA-binding activity to AP-1 sites. We next examined the transcriptional regulatory function of Fra-2 using transient transfection assay in a mouse embryonic carcinoma cell line, F9. The results will be compared with those for two other Fos family proteins, c-Fos and Fra-1.

## MATERIALS AND METHODS

### Library screening

We constructed a chicken cDNA library in  $\lambda$ gt10 using 5  $\mu$ g of poly(A) RNA isolated from CEF that were serum-starved and then treated with 10% calf serum for 60 min in the presence of 10  $\mu$ g/ml cycloheximide. The cDNAs were synthesized with a cDNA cloning kit (BRL) using random primer and a synthetic

oligonucleotide (5'-CTGGCATTGGTCCTCACTCTCTTTCC-TGGA-3') that is located in the 3'-noncoding region of the *fra-2* gene. Recombinants ( $6 \times 10^4$ ) were screened by hybridization with the fragments from exon 1 and exon 4 of *fra-2* genomic DNA (17). From 31 positive clones, several long inserts were subcloned into pUC118 plasmid. From two  $\lambda$  clones ( $\lambda 004$  and  $\lambda 030$ ), the entire coding sequence of *fra-2* cDNA was inserted into pSP64 in the sense orientation to generate pSP-Fra-2. By nucleotide sequence analysis using the dideoxynucleotide chain termination method, the entire coding sequence was shown to be identical to the sequence that had been predicted from the *fra-2* genomic DNA analysis (17) and the deduced amino acid sequence has a strong homology (87%) to human Fra-2 protein (18).

### Plasmids

pSP-c-Fos(rat), pGEM-c-Jun(rat) (10), and pSP-Fra-1(rat) (15) were kindly provided by Dr. T. Curran. pGEM-junB(mouse) and pGEM-junD(mouse) were generous gifts from Dr. D. Nathans (20, 22). Plasmids containing chimeric genes between *c-fos* and *fra-2* were constructed as follows. The *c-fos* gene was first mutagenized to create a BamHI site in the coding region (nucleotide position 556–561 according to the numbering described in 27), which resulted in no substitution of the encoded amino acids. For this purpose, the EcoRI-XhoI fragment of *c-fos* (rat) cDNA was blunt-ended, ligated to XbaI linkers, and cloned into the XbaI site of pUC119 to generate a parent plasmid. The plasmid was hybridized with mutated oligonucleotides, and mutagenized as described previously (28). A clone that generated the BamHI site was isolated and named pUC-*c-fos*M1. The XbaI-BamHI fragment of pUC-*c-fos*M1 which contains the N-terminal portion of the *c-fos* coding region and the BamHI-XbaI fragment of pSP-Fra-2 which contains the C-terminal portion of the *fra-2* coding region were isolated. These fragments were cloned into the XbaI site of pSP64 in the sense orientation to generate pSP-FosF2. The SalI-BamHI fragment of pSP-Fra-2 and BamHI-XbaI fragment of pUC-*c-fos*M1 were ligated to BamHI-XbaI fragment of pSP64 to generate the reciprocal construct, pSP-F2Fos.

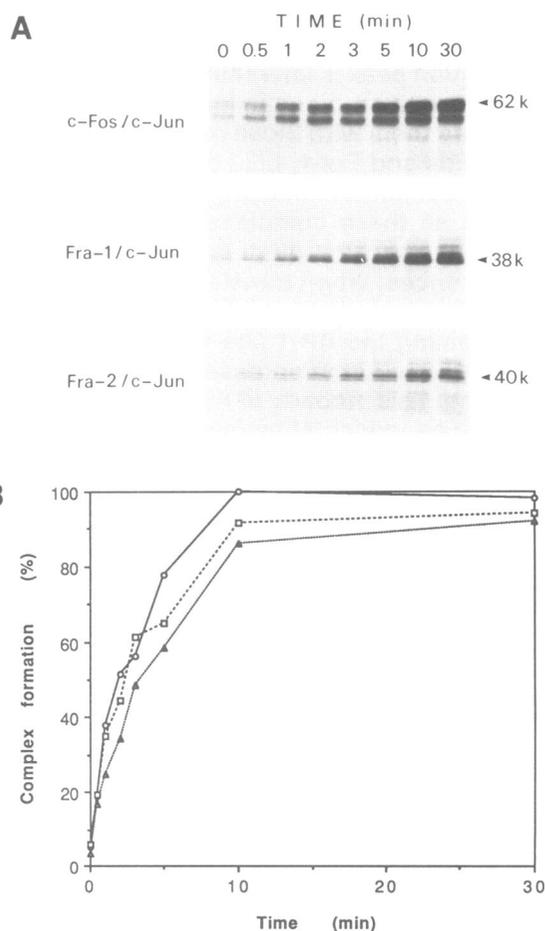

For the construction of expression plasmids, EcoRI-XhoI fragment of *c-fos* (rat) cDNA was blunt-ended, ligated to XbaI linkers and cloned into the XbaI site of the RSV promoter expression vector pRSV-2 (29), kindly gifted by Dr. K. Ozato, to generate pRSV-*c-Fos*. EcoRI-EcoRI fragments of pGEM-*c-Jun*, pGEM-*junB* and pGEM-475-*junD*, as well as EcoRI-XbaI fragment of pSP-Fra-1 were isolated. Each fragment was blunt-ended, ligated to SalI linkers and cloned into the SalI site of pRSV-2. These expression plasmids were designated as pRSV-*c-Jun*, pRSV-*JunB*, pRSV-*JunD*, and pRSV-Fra-1, respectively. The SalI-SalI fragment of pSP-Fra-2, the XbaI-XbaI fragment of pSP-FosF2 and the SalI-XbaI fragment of pSP-F2Fos were also cloned into pRSV-2 in the sense orientation to generate pRSV-Fra-2, pRSV-FosF2 and pRSV-F2Fos, respectively.

To construct the reporter chloramphenicol acetyl transferase (CAT) plasmid used in the transfection experiments, we first constructed a starting plasmid designated proCAT. The Hind-7-Hind-7 fragment of CAT gene (CAT GenBloc (Pharmacia)), the HpaI-BamHI fragment of pSV0CAT (30) (containing SV40 polyA signal) and the BamHI-Hind-7 fragment of p55C1 (31) (containing  $\beta$ -interferon promoter, a kind gift from Dr. T. Taniguchi) were isolated. These fragments were ligated to the PvuII-Hind-7 fragment of pUC19 to generate proCAT. The reporter CAT plasmid, pcolTRECAT was constructed by inserting the synthetic oligonucleotides of col TRE (see the section

entitled gel shift analysis) into the BamHI site of proCAT which is located just upstream of the  $\beta$ -interferon promoter sequence.

### *In vitro* transcription and translation

Plasmid DNAs carrying various cDNAs were linearized by digestion with appropriate restriction enzymes and were transcribed *in vitro* using SP6 RNA polymerase for 1.5 hr at 40°C or T7 RNA polymerase for 1.5 hr at 37°C. Standard reaction mixtures for *in vitro* translation contained 7–12  $\mu$ l of micrococcal nuclease-treated rabbit reticulocyte lysate (Promega Biotech), 0.1  $\mu$ g of transcribed RNA, 1  $\mu$ l of 1 mM amino acids minus methionine and 10  $\mu$ Ci of  $^{35}$ S-methionine. Unlabeled proteins were synthesized in the absence of  $^{35}$ S-methionine in lysates supplemented with 1 mM methionine. The mixtures were incubated for 60 min at 30°C. Labeled protein products were analyzed by SDS-polyacrylamide gel electrophoresis and their radioactivities were measured by using an RI image analyzer (AMBIS).

**Figure 1.** Time course of heterodimer formation between Fos family proteins and c-Jun. (A). Fos family proteins and c-Jun were separately synthesized *in vitro* in the presence or absence of  $^{35}$ S-methionine, respectively. Labeled Fos family proteins and unlabeled c-Jun were combined at similar molecular concentrations and incubated at 37°C. At the time indicated, proteins were immunoprecipitated by anti-Jun antiserum and analyzed by electrophoresis on 10% SDS-polyacrylamide gel. On the right, molecular weights calculated by utilizing comigrated molecular weight markers are shown. (B). Radioactivities in the bands of Fos family proteins shown in (A) were quantitated by using an RI image analyzer. The percentages of Fos family proteins that were recovered in the immunoprecipitates as heterodimers were plotted. Open circles, triangles, and squares indicate *c-Fos/c-Jun*, *Fra-1/c-Jun* and *Fra-2/c-Jun*, respectively.

**Heterodimer formation**

For *in vitro* association, reticulocyte lysates containing Fos family proteins or Jun family proteins were combined at equimolar concentrations and incubated at 37°C. At various times, aliquots were removed and diluted to 100 µl with ice-cold RIPA buffer, and proteins were immunoprecipitated with rabbit polyclonal antiserum such as anti Jun antiserum (32), anti Fra-2 pep 2 antiserum (17) and anti Fos pep 1 antiserum (33). The immunoprecipitation procedure was essentially the same as described (26).

**Gel shift analysis**

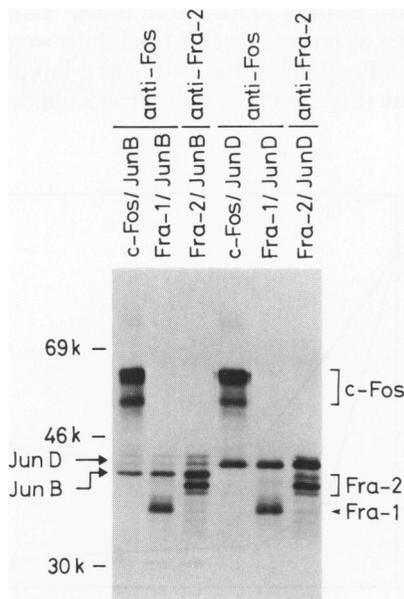

Unlabeled translation products were combined and incubated at 37°C for 30 min, and then 5 µl of binding buffer [10 mM Tris-HCl (pH 8.0), 50 mM MgCl<sub>2</sub>, 1 mM EDTA, 1 mM dithiothreitol (DTT), 5% glycerol, 5% sucrose, 1 mM phenylmethanesulfonyl fluoride (PMSF)] and 1 µg of poly(dI-dC) (Pharmacia) were added. After 15 min at room temperature, <sup>32</sup>P-labeled oligonucleotide probe (0.5 ng) was added and incubation was continued for 15 min. DNA-protein complexes were resolved on a 5% polyacrylamide gel in 1×TBE [50 mM Tris-borate (pH 8.3), 1 mM EDTA] by electrophoresis at 200 V for 2 hr. The sequences of the oligonucleotides used for the probe DNA were as follows. (AP-1-binding sites or related sequences are shown in bold letters.)

**Cell culture and transfection assays**

F9 teratocarcinoma cells were maintained in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% fetal bovine serum (FBS) and were transfected by the modified calcium phosphate coprecipitation method (34). Six hours before transfection, 3 × 10<sup>5</sup> cells were plated in 60 mm dishes with 2.5 ml of medium. The cells were cotransfected with 4 µg of pcolTRECAT as the reporter plasmids and various amounts of expression plasmid(s) carrying the *c-fos*, *c-jun* or a related gene. DNA was brought to 12 µg by addition of the pUC119 plasmid. Sixteen to twenty hours after transfection, cells were washed twice with DMEM and incubated in DMEM containing 10% FBS for 1 day before harvest. Cell lysates were prepared as described previously (30) and protein concentrations were determined by

**Figure 3.** AP-1-binding activity of heterodimers. Each protein was synthesized *in vitro* and mixtures were incubated for 30 min at 37°C. DNA-binding activity was determined by gel shift analysis using 0.5 ng of <sup>32</sup>P-labeled oligonucleotides containing the AP-1 site of FSE2 and collagenase TRE (A) or the AP-1-like sequence from c-jun (c-jun TRE) or somatostatin (somatostatin CRE) genes (B) (Materials and Methods). In samples with competitor (+), unlabeled oligonucleotide (50 ng) was added. Arrowhead indicate the position of the specific bands formed by the protein-DNA complexes.

**Figure 4.** Transactivation of pcolTRECAT reporter plasmid by various combinations of Fos family proteins and Jun family proteins that were transiently expressed in F9 cells. F9 cells were cotransfected with a total of 10 μg of DNA containing pcolTRECAT (4 μg), various amounts of the expression plasmids of c-Jun(A), JunB (B) or JunD (C) and pUC119 as a carrier DNA, without (open circles) or with the expression plasmids of Fos (open triangles), Fra-1 (open squares), or Fra-2 (closed circles) (2 μg). Some of the transfection were carried out in duplicate and the results of two independent experiments are indicated as the average CAT activity.

using a Bio-Rad protein assay kit. CAT activities were assayed by standard methods (30) using cell extracts containing equal amounts of protein. The radioactivities were quantitated by counting  $^{14}\text{C}$  spots on the TLC plate with an RI image analyzer (AMBIS).

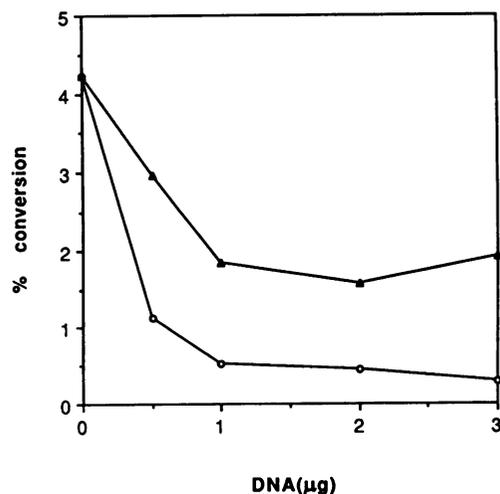

## RESULTS

### Fra-2 forms stable complexes with c-Jun, JunB and JunD

To analyze the complex-forming activity of Fra-2 with c-Jun, Fra-2 and c-Jun were synthesized in rabbit reticulocyte lysates in the presence or absence of  $^{35}\text{S}$ -methionine, respectively. They were mixed at similar molecular concentrations, incubated at 37°C for the time indicated (Fig. 1A) and immunoprecipitated with anti-Jun antiserum. Coimmunoprecipitated Fra-2 protein was detected after gel electrophoresis. Quantitation of the radioactivity (Fig. 1B) clearly indicated that Fra-2 protein forms a stable complex with Jun with similar kinetics to that of c-Fos or Fra-1, and most of the Fra-2 protein forms the complex within 10 min. To examine whether Fra-2 can form complexes with other Jun family proteins, labeled Fra-2 was mixed with labeled JunB or JunD, incubated for 30 min and immunoprecipitated with anti-Fra-2 antiserum. As shown in Fig. 2, JunB and JunD were coimmunoprecipitated with Fra-2, indicating that Fra-2 forms a stable complex with JunB or JunD, as was reported for c-Fos (35). Fra-1 also formed complexes with these Jun family proteins (Fig. 2).

### AP-1-binding activity of Fra-2/Jun family proteins

To analyze whether Fra-2/Jun complex has specific DNA-binding activity, both proteins were separately synthesized *in vitro*, mixed and analyzed by gel shift assay using several  $^{32}\text{P}$ -labelled DNA probes that contain a single AP-1-binding site. As representative AP-1-binding sites, the FSE2 region of the *aP2* gene and an oligonucleotide from the human collagenase gene that contains TPA-responsive element (TRE) were tested. Using these two oligonucleotides as probes, specific band shifts were detected on incubation with Fra-2 plus c-Jun as well as c-Fos plus c-Jun and Fra-1 plus c-Jun (Fig. 3A). The shifted bands almost disappeared

**Figure 5.** Inhibitory effect of Fra-2 or Fra-1 on the transcriptional stimulation by c-Fos plus c-Jun. Expression plasmids of c-Fos and c-Jun (2 μg each) were cotransfected with various amounts (0–3 μg) of Fra-2 (open triangles) or Fra-1 (open circles) expression plasmids on F9 cells. The transactivation was quantitated in the terms of the CAT activity from pcolTRECAT.

upon addition of unlabeled probes as competitors. Furthermore they were not competed out by the mutated FSE2 probe (32) that has two nucleotides conversion in the AP-1 site (data not shown). Control experiments indicated that c-Jun alone does not form a specific band under these assay conditions (Fig. 3A and our unpublished results).

We also tested other DNA probes containing an AP-1-like sequence (one base insertion) that is located in the 5'-flanking region of the chicken *c-jun* gene and a representative cAMP-responsive element (CRE) sequence in the rat somatostatin gene. All of these three complexes were shown to bind to these probes with reduced affinity compared with the binding to the representative AP-1 sites (Fig. 3B). Nucleotides containing these AP-1 like sequences competed the shifted bands of Fig. 3A less effectively, when added to the reaction mixtures instead of homologous competitors (data not shown). Fra-2/JunB and Fra-2/JunD also have an activity to bind these representative AP-1 sites or these two related sequences (data not shown). Even using more sensitive conditions of gel shift assay, we never observed any specific binding by Fra-2 alone, or Fos plus Fra-2, or Fra-1 plus Fra-2 (data not shown).

#### Effect of Fra-2 on transcription from a promoter with an AP-1-binding site

The *in vitro* analysis described above failed to reveal any differences between Fra-2 and other Fos family proteins in their ability either to form a heterodimer with Jun proteins or to bind AP-1 sites as the heterodimer. Since Fos plus Jun transactivate the transcription from a promoter with an AP-1 site much more effectively than Jun alone does, we next examined the effect of Fra-2 on the transcription using transient expression experiments in F9 embryonic teratocarcinoma cells. As a reporter plasmid, we constructed pColTRECAT, which has an AP-1 site from the collagenase gene just upstream of the TATA box from the  $\beta$ -interferon gene and was fused to the CAT gene. The reporter plasmid (4  $\mu$ g) was cotransfected with different amounts of Jun expression vectors with or without Fra-2, c-Fos, or Fra-1 expression vectors (2  $\mu$ g). Even in the absence of c-Fos, c-Jun alone activated the transcription of the reporter CAT gene (Fig. 4A). When combined with Fos expression plasmid, Jun expression plasmid elevated CAT activity, in good agreement

with previous reports (2, 9). On the contrary, Fra-2 plus Jun and Fra-1 plus Jun reduced the CAT activity to a lower level compared with Jun alone. The inhibitory effect of Fra-2 and Fra-1 on gene activation by Jun was observed at all dosages of the transfected Jun plasmid (1 ~ 6  $\mu$ g). This is the first clear difference between Fos and its related antigens in our observations. The stimulatory effect of c-Fos and inhibitory effect of Fra-2 and Fra-1 were further confirmed by a set of transfection experiments in which 0.5 ~ A3  $\mu$ g of expression plasmid of Fos family proteins was cotransfected with a constant amount (2  $\mu$ g) of Jun expression plasmid (data not shown). To test whether Fra-2 or Fra-1 can inhibit the stimulatory effect of c-Jun plus c-Fos, we transfected various amounts of Fra-2 with constant amounts of c-Fos (2  $\mu$ g) and c-Jun (2  $\mu$ g). As shown in Fig. 5, Fra-2 or Fra-1 efficiently suppressed the transactivation by c-Fos/c-Jun in a dose-dependent manner.

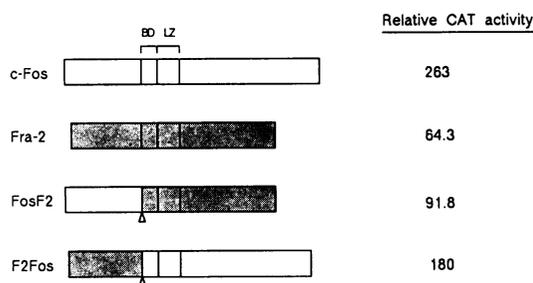

To demonstrate whether this inhibitory effect of Fra-2 and Fra-1 could be observed in conjunction with other Jun family proteins, similar experiments were performed by substituting JunB (Fig. 4B) or JunD (Fig. 4C) for c-Jun. When the transactivation by c-Jun, JunB or JunD homodimers was compared before analyzing the effects of Fos family proteins, Jun was shown to be the most potent transactivator (compare Fig. 4A and B, C). JunB and JunD showed only a weak activity to enhance the transcription from the reporter CAT gene.

When expression plasmids of Fos family proteins were added with JunB expression plasmid, again a clear difference was detected between Fos and its related antigens. Cotransfection with c-Fos enhanced the transactivation of JunB drastically, as described previously (24), while CAT production by Fra-2 plus JunB or Fra-1 plus JunB was kept at as low a level as with JunB alone (Fig. 4B).

We next cotransfected expression plasmids of these three Fos family proteins with JunD expression plasmid. c-Fos enhanced the transactivation by JunD drastically, as was the case with c-Jun or JunB. Interestingly, both Fra-1 and Fra-2 also stimulated the activity, though their stimulatory effects were reproducibly lower than that by c-Fos (Fig. 4C, and unpublished results). These results indicate that both Fra-2 and Fra-1 can modulate transactivation by Jun family proteins either stimulatory or suppressively, depending upon the partner in the heterodimer.

#### Analysis of chimeric proteins between c-Fos and Fra-2

There was clear difference between c-Fos and Fra-2 in their effects on the transactivation by c-Jun (Fig. 4A). c-Fos drastically enhanced the activity, while Fra-2 inhibited it. To analyze whether the distinct behavior of Fos and Fra-2 could be attributable to specific regions of each protein, we next prepared two chimeric constructs, which are mutually reciprocal (Fig. 6). The N-terminus of the basic domain was used as the junction site of recombination. These two chimeric proteins F2Fos and FosF2 were synthesized *in vitro*. Both proteins formed stable complexes with all of the three Jun family proteins and the resultant heterodimers could bind efficiently to AP-1 sites (data not shown). The expression plasmids of these chimeric proteins were cotransfected with Jun expression plasmid and their CAT productions were determined. When their CAT activities were compared with that of c-Jun homodimer, F2Fos inherited the stimulative effect from c-Fos protein, while FosF2 behaved more like Fra-2 (Fig. 6). From these results, we conclude that the difference of properties between Fos and Fra-2 is mainly derived from the C-terminal half of each protein, though there might be small contributions from the N-terminal sequence of each protein.

**Figure 6.** Structures of the chimeric proteins between c-Fos and Fra-2 and their effects on the transactivation by c-Jun. Expression plasmids of c-Fos, Fra-2 and their chimeras (2  $\mu$ g) were transfected with c-Jun expression plasmid (2  $\mu$ g) together with the reporter plasmid pColTRECAT (4  $\mu$ g). Each transfection was carried out in duplicate and the results of two independent transfection experiments are indicated on the right as average relative activity normalized with respect to CAT activity with c-Jun alone, taken as 100. Open triangles indicate the junction of chimeric proteins. BD and LZ indicate basic domain and leucine zipper structure, respectively. Open boxes and stippled boxes indicate the regions derived from c-Fos and Fra-2, respectively.

## DISCUSSION

In this study, Fra-2 protein was shown to bind specifically to AP-1 sites *in vitro* after forming a stable complex with c-Jun, JunB or JunD. Fra-2/c-Jun complex binds four DNA probes containing AP-1 or AP-1-like sequences with a similar affinity to that of c-Fos/c-Jun or Fra-1/c-Jun. Using a reporter plasmid that contains a single AP-1 site of the collagenase gene, Fra-2 was shown to have either a suppressive or a stimulatory effect on the transactivation by Jun family proteins: Fra-2/c-Jun suppresses, while Fra-2/JunD transactivates. This transcriptional regulatory potential is different from that of c-Fos, which stimulates the transactivation by all three Jun family proteins (9, 24, 36). We detected no qualitative difference between Fra-2 and Fra-1 in their transcriptional regulatory potentials. This difference in properties between c-Fos and its related antigens would greatly expand the regulatory potential of the Fos family proteins. It remains to be established whether the regulatory pattern of the matrix between Fos and Jun proteins observed at the AP-1 site of the collagenase gene would also be applicable to AP-1 sites from other genes.

Recently transcriptional activity of another Fos family protein, FosB, as well as its truncated form,  $\Delta$ FosB, was reported (37). Although FosB behaved like c-Fos,  $\Delta$ FosB interestingly had lost the ability in transfection assays to activate a promoter with the AP-1 site of the collagenase gene in combination with any of the three Jun family proteins. It is noteworthy that the inductions of Fra-1 (14), Fra-2 (17), and  $\Delta$ FosB (37) are more prolonged than that of c-Fos after the growth stimulation of fibroblasts by serum. The transient stimulation of transcription from promoters with the AP-1 site(s) of many target genes by c-Fos/c-Jun could be efficiently turned off by the heterodimers between the other Fos family proteins and c-Jun.

The divergence of regulatory activity produced by the combination of Fos and Jun family proteins provides an explanation for the fact that the stimuli-dependent response of a set of genes is controlled by a simple AP-1-binding site DNA sequence. Therefore, precise description of the components of 'AP-1' is essential for understanding the transcriptional regulatory function of this transcription factor in tissues or cell cultures.

## ACKNOWLEDGMENTS

We are especially grateful to Dr. Tom Curran for many helpful discussions and for providing cDNA clones of *c-fos*(rat), *fra-1*(rat), and *c-jun*(rat). We also thank Drs. D.Nathans, K.Ozato and T.Taniguchi for supplying junB and junD cDNAs, pRSV-2 and p55C1, respectively. We thank Dr. M.Nishizawa for advice concerning cDNA isolation and Dr. T.Takeda for the synthesis of oligonucleotides. We thank Ms. E.Suzuki for the preparation of the manuscript. This work was supported by a Research Grant from the Princess Takamatsu Cancer Research Fund and by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science and Culture of Japan.
