Fully epitaxial magnetic tunnel junctions (MTJs) were fabricated with full-Heusler alloy Co$_2$MnSi thin films as both lower and upper electrodes and with a MgO tunnel barrier. The fabricated MTJs showed clear exchange-biased tunnel magnetoresistance (TMR) characteristics with high TMR ratios of 179% at room temperature (RT) and 683% at 4.2 K. In addition, the TMR ratio exhibited oscillations as a function of the MgO tunnel barrier thickness ($t_{MgO}$) at RT, having a period of 0.28 nm, for $t_{MgO}$ ranging from 1.8 to 3.0 nm. © 2008 American Institute of Physics.

[DOI: 10.1063/1.2843756]

Highly spin-polarized electrons are essential for spintronic devices, in which both the charge and the spin of the electron are utilized as the information carrier. Half-metallic ferromagnets (HMFs) are characterized by a complete spin polarization at the Fermi level ($E_F$) due to the existence of an energy gap for one spin direction (usually minority spin) (Ref. 1). The potentially high spin polarization of HMFs is widely advantageous for ferromagnetic electrodes used in spintronic devices in terms of achieving high tunnel magnetoresistance (TMR) ratios in magnetic tunnel junctions (MTJs) and efficient spin injection from ferromagnetic electrodes into semiconductors.

Co-based full-Heusler alloys (Co$_2$YZ) (Ref. 2) have attracted much interest as a preferable ferromagnetic electrode material for spintronic devices. This is because of the HMF nature theoretically predicted for many of these alloys, and because of their high Curie temperatures, which are well above room temperature (RT). In particular, Co$_2$MnSi (CMS) has especially attracted interest because of its half-metallic nature theoretically predicted, with a large energy gap of 0.42 eV (Ref. 3) to 0.81 eV (Ref. 4). Much effort has been dedicated to fabricating and characterizing CMS thin films and also to fabricating MTJs with a CMS as a lower electrode or CMS as both lower and upper electrodes and with an amorphous AlO$_x$ barrier.\textsuperscript{5-10}

We recently developed fully epitaxial MTJs with a Co$_2$YZ thin film [Co$_{50}$Fe$_{50}$Al (CCFA), Co$_2$MnSi (CMS), or Co$_2$MnGe (CMG)] as a lower electrode, and a MgO (001) tunnel barrier.\textsuperscript{11-16} The relatively small lattice mismatch between Co$_2$YZ and MgO for a 45° in-plane rotation (e.g., about −3.7% for CCFA and −5.1% for CMS) enabled us to successfully fabricate fully epitaxial MTJ trilayers featuring highly smooth and abrupt interfaces.\textsuperscript{12-15} We have demonstrated relatively high TMR ratios of 109% at RT (317% at 4.2 K) for CCFA/MgO/Co$_{50}$Fe$_{50}$ MTJs,\textsuperscript{14} 90% at RT (192% at 4.2 K) for CMS/MgO/Co$_{50}$Fe$_{50}$ MTJs,\textsuperscript{13} and 83% at RT (185% at 4.2 K) for CMG/MgO/Co$_{50}$Fe$_{50}$ MTJs.\textsuperscript{16} However, there is much room for further enhancement of the TMR ratio of these fully epitaxial MTJs. Since Co$_2$YZ thin films potentially have a high spin polarization value at RT, a promising approach would be to use these films as both the lower and upper electrodes.\textsuperscript{10,17,18}

In the present study, as an extension of our work on CMS/MgO/Co$_{50}$Fe$_{50}$ MTJs,\textsuperscript{13} we fabricated fully epitaxial MTJs with CMS electrodes as both the lower and upper electrodes and with a MgO tunnel barrier and investigated their TMR characteristics.

We fabricated exchange-biased MTJs. In order to obtain exchange biasing, a CMS upper electrode was used in the antiferromagnetically coupled CMS/Ru/Co$_{50}$Fe$_{10}$ trilayer exchange-biased through the Co$_{50}$Fe$_{10}$/IrMn interface.\textsuperscript{19} The MTJ layer structure was grown on a MgO(001) single-crystal substrate and, from the substrate side, was as follows: MgO buffer (10 nm)/CMS (50 nm)/MgO barrier (0.8–3.4 nm)/CMS (5 nm)/Ru (0.8 nm)/Co$_{50}$Fe$_{10}$ (2 nm)/IrMn (10 nm)/Ru cap (5 nm). Each layer in the MTJ layer structure was successively deposited in an ultrahigh vacuum chamber (base pressure of $\sim$6×10$^{-8}$ Pa) using magnetron sputtering and electron beam (EB) evaporation. The CMS lower electrode was deposited by magnetron sputtering at RT and subsequently annealed \textit{in situ} at 600 °C, for which we have already confirmed the L$_2$$_1$ structure formation from x-ray pole figure measurements.\textsuperscript{5} The upper CMS electrode was also deposited at RT and subsequently annealed \textit{in situ} at up to 600 °C. An appropriate temperature for \textit{in situ} annealing just after the deposition of an upper CMS electrode ($T_a$) is critically important for fabricating high-performance MTJs with a CMS film as the upper electrode, i.e., a higher $T_a$ would be favorable for obtaining a high spin polarization of the upper CMS film through the improvement of structural properties, and a $T_a$ that does not cause the diffusion problem is also required. Given these guidelines, we fabricated CMS/MgO/CMS MTJs (hereafter, CMS-MTJs) with $T_a$ ranging from 400 to 600 °C.

ing photolithography and Ar ion milling. The fabricated MTJs with the layer structure described above used in situ optical emission spectroscopy. We observed the TMR ratio at RT increased significantly with increasing T_a. The values of 179% at RT and 683% at 4.2 K. These values are significantly higher than the 90% at RT and 192% at 4.2 K. The CMS and MgO dependence of TMR ratio shows clear exponential dependence on t_MgO range from 1.7 to 3.0 nm, indicating typical tunnel magnetoresistance curves at RT and 4.2 K for a fully epitaxial CMS/MgO/CMS MTJ with T_a of 600 °C. The junction size was 10×10 μm². The bias voltage was 1 mV. The TMR ratio versus t_MgO dependence of CMS MTJ with MgO shown in Fig.3 suggests os-suit annealing at around 550 to 600 °C considerably increased the tunneling spin polarization of the upper CMS electrode through the improvement of structural properties.

Figure 2(b) shows typical TMR curves at RT and 4.2 K for a fully epitaxial CMS/MgO (2.1 nm)/CMS MTJ with T_a of 600 °C. The junction size was 10×10 μm². The bias voltage was 1 mV. The TMR ratio versus t_MgO dependence of CMS and MgO panel barriers for a relatively wide range from 1.8 to 3.0 nm, and the TMR ratio and it saturated for T_a ranging from 550 to 600 °C. The marked increase of the TMR ratio with increasing T_a suggests that in situ annealing at around 550 to 600 °C considerably increased the tunneling spin polarization of the upper CMS electrode through the improvement of structural properties.

Figure 2(a) shows typical TMR curves at RT and 4.2 K for a fully epitaxial CMS/MgO/CMS MTJ fabricated on a 20×20 mm² MgO (001) substrate, where R_P and R_AP are the respective tunnel resistances for the parallel and antiparallel magnetization configurations between the upper and lower electrodes. The nominal junction size was 10×10 μm². The bias voltage was 5 mV. Both R_P and R_AP showed clear exponential dependence on t_MgO range from 1.7 to 3.0 nm, indicating typical tunnel junction behavior.

Figure 3(a) shows typical TMR ratio dependence of R_P and R_AP as a function of t_MgO, where the TMR ratio is defined as (R_AP−R_P)/R_P. The MTJs exhibited relatively high TMR ratios of over 110% at RT for a wide range from 1.8 to 3.0 nm, and the TMR ratio gradually increased from 112% to 147% for this range. The TMR ratio versus t_MgO shown in Fig. 3(b) suggests oscillations of the TMR ratio as a function of t_MgO for t_MgO ranging from 1.8 to 3.0 nm. In Fig. 3(b), a fitting line for the TMR ratio versus t_MgO with a single period of 0.28 nm is plotted as a guide, and the period dependence of the TMR ratio is relatively well represented by this fitting curve. The oscillation period of 0.28 nm is close to the oscillation period of 0.32 nm for the oscillatory t_MgO dependence of R_P and R_AP. 

FIG. 1. RHEED patterns along the azimuths of [100]MgO and [110]MgO (corresponding to [110]CMS and [100]CMS, respectively), observed in situ for each successive layer in the Co_MnSi CMS/MgO/CMS trilayer structure during fabrication. (a) A lower CMS electrode deposited at RT and annealed in situ at 600 °C, (b) a MgO tunnel barrier, and (c) an upper CMS electrode deposited at RT and annealed at 500 °C. The lower and upper CMS electrodes both show additional streak patterns (indicated by arrows), showing that both had the L2₁ structure.

FIG. 2. (Color online) (a) TMR ratios at RT for CMS/MgO/CMS MTJs as a function of annealing temperature for CMS/MgO/CMS MTJs with T_a of 600 °C. The junction size was 10×10 μm². The bias voltage was 1 mV.
observed for fully epitaxial Fe/MgO/Fe MTJs.\textsuperscript{20,21} We could not extract the oscillatory components of \( R_P \) and \( R_{AP} \) for the fabricated CMS-MTJs. To observe possible oscillations of \( R_P \) and \( R_{AP} \) as a function of \( t_{\text{MGO}} \), the degree of the junction area scattering should be lower than the amplitudes of the oscillatory components of \( R_P \) and \( R_{AP} \). But this condition was probably not satisfied in the fabricated MTJs. (The MTJ junction size was defined with photolithography.) On the other hand, the junction area scattering does not affect the TMR ratio because that the TMR ratio calculated as \( (R_{AP}−R_P)/R_P \) is a quantity independent of the junction area. Therefore, the observation of oscillations of the TMR ratio as a function of \( t_{\text{MGO}} \) is easier than that of oscillations of \( R_P \) and \( R_{AP} \). To clarify the mechanisms of the observed oscillatory dependence of the TMR ratio, further systematic study for fully epitaxial MTJs with Heusler alloy electrodes and a MgO barrier is needed.

Finally, we will discuss possible reasons for the enhancement of the TMR ratios of the presented MTJs with CMS electrodes and with a single-crystalline MgO barrier compared with previously reported MTJs with a CMS electrode or CMS electrodes and with an amorphous \( \text{AlO}_x \) barrier.\textsuperscript{8–10} First, our approach of growing fully epitaxial MTJ layer structures enables the growth of single-crystalline lower and upper Co\textsubscript{2}YZ electrodes. Then, the high-quality single-crystalline Co\textsubscript{2}YZ electrodes would lead to a high spin polarization of each ferromagnetic electrode. Second, fully epitaxial MTJ layer structures are advantageous for forming atomically flat and abrupt interfaces in MTJ trilayers. As a result, the high spin polarization of potentially half-metallic CMS thin films is retained at the interfaces. Third, the combination of single-crystalline Co\textsubscript{2}YZ thin films as lower and upper electrodes with a single-crystalline MgO tunnel barrier enables the enhancement of the tunneling spin polarization due to preferential tunneling of electrons with \( \Delta_1 \) symmetry.\textsuperscript{22–24} Fourth, depositing MgO barriers by EB evaporation in a ultrahigh vacuum chamber ensures that the interfacial region of CMS lower electrodes with a MgO barrier is not oxidized, which has been demonstrated directly by x-ray absorption spectroscopy and x-ray magnetic circular dichroism.\textsuperscript{25}

In summary, we fabricated fully epitaxial MTJs with full-Heusler alloy CMS thin films as both lower and upper electrodes and with a MgO tunnel barrier. The fabricated MTJs demonstrated high TMR ratios of 179\% at RT and 683\% at 4.2 K. The demonstrated high TMR ratios confirm the promise of a single-crystalline CMS film with a combination of a single-crystalline MgO tunnel barrier as ferromagnetic electrodes in spintronic devices.
