\textit{Keywords}: poly-fluorination, adamantane, bromine trifluoride

\textbf{Abstract}

The direct fluorination reaction of the functionalized adamantanes was achieved by using \( \text{BrF}_3 \). In the reaction with methyl adamantane-1-carboxylate 1 and dimethyl adamantane-1,3-dicarboxylate 3, three and two fluorine atoms, respectively, were introduced selectively to their \textit{tert}-carbons. On the other hand, in the reactions with 1-acetoxyethyladamantane 5, and 2-adamantanone 9, not only the expected fluorination of their \textit{tert}-carbons, but also unexpected reactions such as fluorination of carbonyl functionality occurred.

\textbf{1. Introduction}

Adamantane is a simple cage compound consisting of four \textit{tert}-carbons and six \textit{sec}-carbon atoms. Bioactive derivatives of adamantane are known, and 1-aminoadamantane (amantadine) and 1-amino-3,5-dimethyladamantane (memantine) have medicinal uses [1]. Introduction of fluorine atoms in bioactive compounds can enhance their activities and reduce undesirable side-effects. Therefore, the synthesis of
fluorinated adamantane derivatives has received significant attention [2]. Recently, we reported the direct fluorination of adamantanes by an electrochemical method [3]. One to three fluorine atoms can be introduced selectively on the tert-carbons of the adamantanes by controlling the conditions, and functional groups such as ester or cyano groups could survive under the conditions. However, a drawback is that special equipment is required for the electrochemical reaction. Therefore, we also studied the fluorination of adamantanes by non-electrochemical methods, and succeeded in the fluorination of adamantanes with IF₅, without the special equipment needed for electrolysis [4]. However, owing to the inherent reactivity of IF₅, only one or two fluorine atoms could be introduced. Moreover, when electron-withdrawing groups were attached on the substrate, fewer (or no) fluorine atoms could be introduced. For example, 1-cyanoadamantane and dimethyl adamantane-1,3-dicarboxylate were inert to IF₅, and only one fluorine atom could be introduced to methyl adamantane-1-carboxylate. For the introduction of more fluorine atoms to adamantane derivatives with low reactivity, a more reactive fluorination reagent than IF₅ is required [5]. Herein, we report the direct fluorination of adamantanes using BrF₃ [6], which is more reactive than IF₅ [8].

2. Results and discussion

Initially, the reaction of methyl adamantane-1-carboxylate 1 with BrF₃ was performed. The reaction proceeded even at -78 °C, and three fluorine atoms were introduced to its tert-carbons (Entry 1 in Table 1). The best result was obtained by performing the reaction using 4 eq of BrF₃ at 0 °C for 3 h, and methyl 3,5,7-trifluoroadamantane-1-carboxylate 2 was obtained in 88% yield (Entry 3). These results demonstrated the higher reactivity of BrF₃ compared to IF₅ in the direct fluorination reaction of the adamantanes.

Next, we applied BrF₃ to the fluorination of dimethyl adamantane-1,3-dicarboxylate 3, which was inert to IF₅, and obtained dimethyl 5,7-difluoroadamantane-1,3-dicarboxylate 4 in 86 % yield (Entry 2 in Table 2). Unexpected reactions also occurred during the fluorination reaction using BrF₃. When 1-acetoxyethyladamantane 5 was reacted with BrF₃ at -78 °C for 0.5 h, two fluorine atoms were selectively introduced and 1-acetoxyethyl-3,5-difluoroadamantane 6 was obtained in 94 % yield (Entry 3). On the other hand, when the reaction was carried out at 0 °C for 6 h, three fluorine atoms were introduced and 1-acetoxyethyl-3,5,7-trifluoroadamantane 7 was obtained in 62 % yield (Entry 4). However, unexpectedly, 1-(((1,1-difluoroethoxy)methyl)-3,5,7-trifluoroadamantane 8 was also formed in 14 % yield. Under these conditions, the fluorination of the carbonyl group also occurred [9]. In the reaction with 2-adamanthone 9, a mixture of
tetrafluorinated compounds 10 and 11 was obtained (Entry 5). Rearrangement of the carbonyl group occurred in addition to the fluorination of the carbonyl group and tert-carbons [11] (Scheme 1).

Scheme 1. Plausible mechanism for the formation of 10 and 11

These unexpected reactions were due to the high reactivity of BrF₃, and were not observed in the case of IF₅.

\(^a\)If otherwise not mentioned, the reaction was carried out in CH$_2$Cl$_2$ using 4 eq of BrF$_3$.

\(^b\)Isolated yield based on 1 used. In parentheses, $^{19}$F NMR yield.
1-((1,1-difluoroethoxy)methyl)-3,5,7-trifluoroadamantane 8 was also formed in 14% yield.

3. Conclusion

Various functionalized adamantanes were reacted with BrF₃, and two to three fluorine atoms were introduced selectively on their tert-carbons. Even when less reactive substrates such as methyl adamantan-1-carboxylate 1 or dimethyl adamantane-1,3-dicarboxylate 3, were used, multiple fluorine atoms were introduced to their tert-carbons. On the other hand, in the reaction of 1-acetoxymethyladamantane 5 and 2-adamantanone 9, unexpected reactions occurred, such as the fluorination of carbonyl group, and rearrangement.

4. Experimental

4.1. General

The melting points were measured with a Yanagimoto micro melting-point apparatus. The IR spectra were recorded using a JASCO FT/IR-410. The ¹H NMR (400 MHz) spectra, ¹⁹F NMR (376 MHz) spectra, and ¹³C NMR (100 MHz) were recorded in CDCl₃ on a JEOL JNM-A400II FT NMR and the chemical shift, δ, is referred to TMS (¹H, ¹³C) and CFCl₃ (¹⁹F), respectively. BrF₃ in a cylinder was purchased from Galaxy Chemicals, LLC and used without purification. BrF₃ was transferred from cylinder to a
Teflon™ bottle through a Teflon™ tube using nitrogen pressure, and a small quantity of BrF₃ in a small Teflon bottle was kept in a freezer [12]. It decomposes in air by humidity emitting HF fume and was handled in a bench hood with rubber-gloved hands under atmosphere of nitrogen. It is highly reactive and a special care is required for its use. BrF₃ is stable in glassware but the reaction was carried out in a centrifuge tube of Teflon™ FEP with a tight screw cap because generation of HF occurs during the reaction.

4.2. Fluorination of adamantane derivatives by BrF₃.

**Methyl 3,5,7-trifluoroadamantane-1-carboxylate (2):** To a CH₂Cl₂ solution (1.5 mL) of BrF₃ (378 mg, 2.76 mmol) in a Teflon™ FEP reactor, methyl adamantane-1-carboxylate (134mg, 0.69 mmol) in CH₂Cl₂ (0.8 mL) was added at -78 °C through a Teflon™ cannula and the mixture was stirred at 0 °C for 2h. Then the mixture was cooled to -78 °C again, and 2mL of Me₃SiCl was added slowly to decompose the excess of BrF₃. The mixture was brought up to room temperature and neutralized with aq NaHCO₃. The mixture was extracted with CH₂Cl₂ (20 mL X 3) and the combined organic phase was washed with aq Na₂S₂O₃ and dried over MgSO₄. After concentration under reduced pressure, 2 was isolated by column chromatography (silica gel, hexane-ether) in 88 % yield. mp 109–112 °C (sealed tube) (lit.[2] 108.5-110 °C); IR (KBr) 2958, 1737, 1339, 1259, 1226, 964 cm⁻¹; ¹H NMR (400 MHz, CDCl₃) δ 3.74 (s, 3H), 2.16–1.99 (m, 12H); ¹⁹F NMR (376 MHz, CDCl₃) δ -144.00 (s, 3F); ¹³C NMR (100MHz, CDCl₃) δ 173.4 (q, 4J_C,F = 3.4 Hz), 91.7 (dt, ¹J_C,F = 191.2, ³J_C,F = 15.3 Hz, 3C), 52.6, 46.6-46.0 (m, 3C), 43.2 (q, ³J_C,F = 11.8 Hz), 42.1–41.7 (m, 3C); HRMS (EI) calcd for C₁₂H₁₅O₂F₃ 248.1024, found 248.1013.
