ABSTRACT
This paper presents the performances of L-shape shear connector subjected to strut compressive force in steel-concrete composite structures. L-shape shear connectors were found to fail in two different failure modes, split failure mode, and concrete crushed/shear failure mode depending on the direction of the strut compressive force. There existed a critical strut angle separating the two different failure modes, and it was found to have a linear relationship with the thickness to height ratio of the shear connector. Meanwhile, a design equation for the ultimate shear capacity of the shear connector for each failure mode was developed and proposed. It was confirmed that the shear force-relative displacement relationship could be represented by a unique enveloped curve by normalizing the shear forces by the ultimate shear force and the relative displacements by the height of the shear connector. Thus, an exponential equation to predict the enveloped curve was proposed while the ultimate relative displacement was found approximately 0.02 times the height of the shear connectors regardless of the sizes of the shear connector, the concrete strength, and the strut angle.

Keywords: L-shape shear connector, strut compressive force, shear force, relative displacement.

1. INTRODUCTION
L-shape shear connector is one of shear connector type which is usually used to transfer shear force from steel to concrete and vice versa in steel-concrete composite structures. The equation to predict the shear capacity of L-shape shear connector was previously given by (JSCE 1992 and 2006). However, according (Soty and Shima 2010 and 2011), the equations given by (JSCE 1992 and 2006) were found to underestimate the shear capacity of L-shape shear connector subjected to strut compressive force. Then a new equation was subsequently developed and proposed. They (Soty and Shima 2010) proposed not only the equation to predict the shear capacity but also that to predict the shear force-relative displacement relationship of L-shape shear connector based on the experimental results of 1st series specimens and the FEM analyses results. However, their equations were proposed only in case of strut angle of 45° and splitting crack controlled the final failure mode.

Therefore, this paper integrates the experimental results of (Soty and Shima 2010) with the test results of a 2nd series specimens whose strut angles are smaller than 45° ($\theta < 45^\circ$) in order to

* Corresponding author: Email: ros.soty@kochi-tech.ac.jp
propose new equations for the ultimate shear forces of L-shape shear connector $V_u$ at split failure and at shear failure. This paper also proves the applicable ranges of the formula of the enveloped curve of shear force-relative displacement relationship of the shear connectors which was previously proposed by (Soty and Shima 2010) in case of different failure modes and strut angles.

2. EXPERIMENT

The specimens are symbolized as S-height of specimen-height of shear connector-thickness of shear connector-concrete strength-strut angle (S-h-hc-t1,sc-fc'-θ). Figure 1 and Table 1 give the detail of both the 1st and the 2nd test series specimens including the shear connector and the support. JIS G 3101 standard steel with grade SM490 ($f_y=370$N/mm$^2$, $f_u=511$N/mm$^2$ and $E=204$kN/mm$^2$) and grade SS400 ($f_y=352$N/mm$^2$, $f_u=448$N/mm$^2$ and $E=202$kN/mm$^2$) was used for the steel skin plate and the shear connector, respectively. The mix proportions of concrete used for all specimens are summarized in Table 2.

Strain distributions in the skin plate in front of the shear connector were measured by strain gauges of 5 mm long, R1-R2 and R3-R4 attached on both sides of the skin plate as shown in Figure 2a. However, differently from the 1st test series specimens, strain gauges R5-R6 were also mounted on both sides of the shear connectors in the 2nd test series specimens. The distribution of concrete-skin plate slip in front of the shear connector was measured by means of the displacement transducers as illustrated in Figure 2b. The average value given by LD1-LD4 was determined as the slip. Figure 2c illustrates how the relative displacements between the top and the bottom of the shear connector $δ$

Figure 2: (a) Locations of strain gauges; (b) Slip measurement location; (c) Locations of displacement transducers for relative displacement measurement.

were measured. The strain gauges and the displacement transducers were installed left-right symmetrically in pairs in all specimens. The specimens were loaded and unloaded with an increment of 30kN; meanwhile, the load $P$ and the data from the strain gauges and the displacement transducers were recorded until failure of the shear connector.

3. PERFORMANCE OF L-SHAPE SHEAR CONNECTOR

3.1. Failure Mode

L-shape shear connectors were found to fail with different failure modes, split failure, shear-split failure, concrete crush, and shear failure were identified. The conditions of the shear connectors at failures observed in the 2nd test series specimens are illustrated in Figure 3. The experimental results showed that the possibility of split failure and concrete crush or shear failure depended on the strut angle $\theta$ and the size of the shear connector. Accordingly, the relationships between $\theta$ and $t_{1,sc}/h_{sc}$ of all tested specimens were plotted in Figure 4. The experimental results suggested that split failure mode and concrete crush or shear failure mode of the shear connector can be separated by a border line of a critical strut angle $\theta_o$ which is a function of $t_{1,sc}/h_{sc}$ as expressed in equation (1).

$$\theta_o = -210 \times \left(\frac{t_{1,sc}}{h_{sc}}\right) + 41$$  \hspace{1cm} (1)

Where, $\theta_o$: critical strut angle (deg), $t_{1,sc}$: thickness of the shear connector, and $h_{sc}$: height of the shear connector.

It means that split failure mode and concrete crush or shear failure mode would occurred when strut angle $\theta > \theta_o$ and $\theta \leq \theta_o$, respectively.
The different performance of L-shape shear connectors subjected to strut compressive force $F$ failed in split failure mode and in concrete crush or shear failure mode can be simply explained by Figures 5a and 5b and Figures 5c and 5d, respectively. As shown in Figure 5a, when $\theta > \theta_0$ the concrete in front of the shear connector seemed to resist against multi-direction stresses; and the release of the principal tensile stress $\sigma_t$ depended on the relative displacement $\delta$. Then, when the relative displacement reached its ultimate value $\delta_u$, splitting crack took place in the concrete along the compressive strut axis perpendicular to the principal tensile stress direction, Figure 5b.

Differently, as shown in Figure 5c, when $\theta \leq \theta_0$, the concrete in front of the shear connector was forced to relocate from the crushing point and moved along the direction of the principal tensile stress $\sigma_t$. This mechanism induced a vertical confinement of concrete in front of the shear connector and resulted in high tensile stress in the vertical part of the shear connector. Due to the vertical confinement upon the concrete, due to the relative displacement of the shear connector, and due to the strut compressive force with $\theta \leq \theta_0$, the concrete in front of the shear connector failed in concrete crush or shear failure mode at ultimate relative displacement $\delta_u$ and at a shear compressive
stress \( \tau \) forming a shear plane as shown in Figures 3d and 5d.

![Shear Plane Diagrams](image)

\( \delta \) (mm) before split failure, \( \delta_u \) (mm) at split failure, \( \delta \) (mm) before shear failure, \( \delta_u \) (mm) at concrete crush or shear failure

**Figure 5: L-shape shear connector with (\( \theta > \theta_o \)) and with (\( \theta \leq \theta_o \)).**

### 3.2. Ultimate shear force

Table 3 gives a summary of the ultimate shear forces \( V_u \) obtained from experimental results and calculation results \( V_{sc1} \) by means of the formula given by (JSCE 2006) with all safety factors 1.0. It can be observed that \( V_u / V_{sc1} \) was found up to 1.69 when \( \theta \) was small. This meant that JSCE’s equation gave a conservative prediction. Similarly, the shear force \( V_{sc2} \) predicted by means of the equation given by (Soty and Shima 2010) was also found conservative when \( \theta < 45^\circ \) with \( V_u / V_{sc2} = 1.25 \). Therefore, new formulas for the ultimate shear forces of L-shape shear connectors \( V_u \) failed in split failure mode and in concrete crush or shear failure mode are necessary. Based on a simplified model given in Figure 6, the formulas to predict the shear capacity of the shear connector were developed and proposed as follows:

\[
V_u = k \left( f'_c \right)^{0.5} b_{sc} \times h_{sc} \times \cos \theta
\]

\[
k = 28 \left( t_{sc} / h_{sc} \right) + 0.7 \quad \text{if} \quad \theta > \theta_o
\]

\[
k = 36 \left( t_{sc} / h_{sc} \right) + 0.66 \quad \text{if} \quad \theta \leq \theta_o
\]

Where, \( V_u \): ultimate shear force in concrete crush or shear failure mode (N), \( b_{sc} \): width of shear connector (mm), \( h_{sc} \): height of shear connector (mm), \( t_{sc} \): thickness of shear connector (mm), \( f'_c \): concrete compressive strength (N/mm\(^2\)), and \( \theta \): strut angle (\( \theta \leq \theta_o \)) (degree).

It can be seen in Table 3 that equation (2) can precisely predict the ultimate shear force with \( V_u / V_{u,Eq2} \) varied from 1.00 to 1.04.

3.3. Shear force-slip relationship

As shown in Figure 7, it was found that slip between concrete and skin plate in front of the shear connector appeared even under low load levels. Similar results were also found by (Kiyomiya et al. 1986), (Ueda and Chin 1989), and (Chuah et al. 1991). However, L-shape shear connectors in beam type specimens were found to have shear resistance even though the diagonal crack already appeared in the concrete from the head of the shear connector. These results proved the advantage of the test method as compared to push-out and pull-out test methods. Based on the experimental results of (Kiyomiya et al. 1986), (Ueda and Chin 1989), and (Chuah et al. 1991), the shear connectors in push-out and pull-out tests gradually lose their shear resisting abilities after crack appeared in the concrete from the head of the shear connectors. Meanwhile, no effect of shear connector height on shear force-slip relationships was observed. However, based on the experimental results, the failure mode of the shear connector and the strut angle were found to have an effect on the ultimate shear force and the ultimate slip.

![Figure 7: Shear force-slip relationships.](image7)

![Figure 8: V-δ relationships.](image8)

3.4. Shear force-relative displacement relationship

It can be observed in Figure 8 that large increment of relative displacement with small increment of shear force appeared after the diagonal crack appeared from the head of the shear connector. These results indicated that the stiffness of the shear connector was suddenly reduced by the occurrence of
the first diagonal crack. These similar behaviors were also observed in steel-concrete sandwich beams by (Saidi et al. 1999 and 2008). More importantly, the experimental results suggested that the relative displacement of the shear connector has a great influence on its shear resisting capacity. The displacement of the head of the shear connector caused a release of the principal tensile stress generated in the concrete in front of the shear connector. This phenomenon limited the level of shear force on the shear connector. Therefore, the relative displacement of the shear connector has to be carefully controlled in design. Advantageously, the ultimate relative displacements $\delta_u$, the displacement which caused failure of shear connector, and the ultimate shear forces $V_u$ of L-shape shear connectors were obtained in this study.

3.5. Formulation for shear force-relative displacement relationship

The formula for shear force-relative displacement relationship of L-shape shear connector subjected to strut compressive force was previously given by (Soty and Shima 2010). It was proposed only in case of $\theta = 45^\circ$ and for the case after the occurrence of diagonal crack from the head of the shear connector until failure of the shear connector, where the shapes of the curves were experimentally clearly observed. The equation was given as follows:

$$V/V_u = (1 - \exp(-180 \times (\delta/h_{sc})))^{0.6}$$

(5)

Where, $V_u$: ultimate shear force of the shear connector (N), $\delta$: relative displacement (mm), and $h_{sc}$: height of shear connector (mm).

Figure 9 gives $V/V_u$ and $\delta/h_{sc}$ relationships of the 1$^\text{st}$ and the 2$^\text{nd}$ test series specimens with different strut angle and failure mode. It can be observed that good agreements between the experimental results and the calculation results by means of equation (5) were also observed regardless of the strut angle and the size of the shear connector. Therefore, these results implied that equation (5) could be used to predict the enveloped curve of shear force-relative displacement relationships of L-shape shear connector regardless of the size of the shear connector, the strut angle, the concrete strength, and the final failure mode. Meanwhile, $\delta_u$ was confirmed to be equal to $0.02h_{sc}$.

![Figure 9: $V/V_u - \delta/h_{sc}$ relationships.](image)
4. CONCLUSIONS

(1) L-shape shear connectors under strut compressive forces in steel-concrete composite structures were found to have different failure modes namely split failure mode and concrete crush or shear failure mode. Both final failure mode and shear resisting mechanisms of the shear connector were found to be controlled by the strut angle and the thickness to height ratio of the shear connector.

(2) There existed a critical strut angle $\theta_0$ separating split failure mode from concrete crush or shear failure mode regardless of concrete strength. The equation of $\theta_0$ was found to be linear whose equation was a function of thickness to height ratio of the shear connector as given in equation (1).

(3) The equation to predict the ultimate shear capacity $V_u$ of L-shape shear connector subjected to strut compressive force was developed and proposed as appeared in equation (2). However, the applicable ranges of the proposed equations are only in the interval of strut angle $20^\circ \leq \theta \leq 45^\circ$.

(4) Regardless of the size of the shear connector, the concrete strength, and the strut angle, the relationship between shear force and relative displacement of L-shape shear connector can be represented by a unique enveloped curve by normalizing the shear forces by the ultimate shear force and the relative displacements by the height of the shear connector for the case after the occurrence of diagonal crack from the head of the shear connector until failure of the shear connector. The ultimate relative displacements $\delta_u$ of L-shape shear connectors was found approximately 0.02 times the height of the shear connector.

(5) By means of this research results, the applicable ranges of equation (5) was extended to be applicable to predict the enveloped curved of shear force-relative displacement relationship of L-shape shear connector despite different shear connector sizes, concrete strength, and strut angle.
