ABSTRACT

The numerical simulation of the crack welding process is reported in this paper. The thermo-electro-structural coupled-field finite element analysis is adopted to investigate the welding process of crack surfaces. In the simulation, the pressure-dependent and temperature-dependent electrical contact conditions are considered. From the results, the crack surfaces can melt and weld together under the compressive load and electric current. The contact pressure effect must be considered in the finite element analysis to obtain more practical results.

Keywords: crack welding, contact pressure, Joule heating, finite element, coupled-field.

1. INTRODUCTION

Due to the Joule heating effect, hot regions at the crack tip or crack surface can be induced under the compressive load and electric current. Many studies have reported that the Joule heating effect can induce local compressive thermoelastic stresses and melting area at the crack tip arresting crack propagation (Kudryavtsev et al. 1982; Parton and Kudryavtsev 1988; Cai and Yuan 1999; Fu et al. 2001; Hasanyan et al. 2005; Qin et al. 2007).

Similar to the resistance spot welding process, the crack surfaces can melt and weld together under the Joule heating. In this paper, the crack welding process will be studied by the thermo-electro-structural finite element analyses with the software ANSYS 14.0. Based on the author’s previous studies (Liu 2008; Liu 2011a; Liu 2011b), the crack contact conditions are considered in the simulations. The temperature fields will be obtained for estimating the crack welding behaviors.

2. CASE STUDY

Figure 1 shows the configuration of the case study. A metal plate with a central crack is subjected to the compressive force $F_0$ and DC current $i_0$. This thin plate is made of mild steel with dimensions $2W \times 2L \times e$. The crack length is $2a$. The thermo-electro-structural coupled-field problem in Fig. 1 will be solved by the finite element method. The plane stress, two-dimensional thermo-electric

conditions, isotropic properties are assumed. To simulate more practical conditions, the temperature-dependent material properties in Table 1 (Tsai et al. 1991) are adopted in the analysis. Also, the elasto-plastic stress-strain properties in Fig. 2 are considered. The electric-current-induced thermo-structural problem is transient. The initial temperature is 21 °C. From the conclusion of Liu (2011a), the phase change effect can be ignored.

The electrical-thermal-mechanical contact conditions between crack surfaces are considered in this study. The electric current and heat flow can pass through the crack surfaces when the crack contact occurs. Figure 3 shows the pressure-dependent and temperature-dependent electrical contact conditions considered in the simulations (Sun and Dong 2000). The symbol \( \eta_{\text{cel}} \) is the electrical conductance of the contact surfaces.

3. METHODS OF ANALYSES

In this study, the finite element equations of the thermo-electro-structural coupled-field analysis are listed as follows (ANSYS, Inc. 2011):

\[
\begin{bmatrix}
M & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\dot{U} \\
\dot{T} \\
\dot{V}
\end{bmatrix}
+ 
\begin{bmatrix}
C & 0 & 0 \\
C^u & C^t & 0 \\
0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\dot{U} \\
\dot{T} \\
\dot{V}
\end{bmatrix}
+ 
\begin{bmatrix}
K & K^u & 0 \\
0 & K^t & 0 \\
0 & 0 & K^v
\end{bmatrix}
\begin{bmatrix}
U \\
T \\
V
\end{bmatrix}
= 
\begin{bmatrix}
F \\
Q \\
I
\end{bmatrix}
\]  

(1)

where \(U, T, V, F, Q\) and \(I\) are the vector forms of the displacement, temperature, electric potential, force, heat flow rate and electric current, respectively. The material constant matrices \(M, C, C^1, C^{tu}, K, K^t, K^{ut}\) and \(K^v\) are the structural mass, structural damping, thermal specific heat, thermo-structural damping, structural stiffness, thermal conductivity, thermo-structural stiffness and electric conductivity, respectively. The coupled heat flow matrix \(Q\) contains the effects of the thermal loading and electrical Joule heating. \(C^{tu}\) and \(K^{ut}\) are thermo-structural coupled terms. Eq. (1) is a directly coupled nonlinear equation which is solved using the Newton-Raphson iterative method.

Figure 3: Pressure-dependent and temperature-dependent electrical contact conditions.

Figure 4: Finite element model. (a) half model, (b) local mesh.
The finite element model of the previous study (Liu 2008) is adopted in this paper. The accuracy of the mesh has been validated by Liu (2008). Fig. 4 shows the finite element mesh of ANSYS with \( W=L=0.05 \) m and \( a=0.01 \) m. Due to the symmetry of the problem, only a half plate of Fig. 1 is analyzed. The symmetric conditions are applied on the finite element model. The plate is modeled by ANSYS element type: PLANE223, i.e. the 8-node isoparametric plane element with the thermo-electro-structural coupled-field analysis. The plane stress option is used due to the thin thickness (\( e=0.001 \) m). In Fig. 4, the model has 1822 elements and 5353 nodes. The quarter-point elements (QPE) (Barsoum 1976) are used for modeling the \( r^{-1/2} \) singularity at the crack tip.

4. RESULTS AND DISCUSSIONS

4.1. Hot regions due to Joule heating

To investigate the temperature field on the plate, the external loads \( i_0=25000 \) A and \( F_0=0 \) N are applied on the plate boundary. The total operating time is 0.06 s. As a result, Figure 5 shows that the temperature at the crack tip increases with time. In Fig. 6, it can be seen that the Joule heating effect causes a high temperature area at the crack tip. It demonstrates the existence of the melting crack tip (red color area) when enough electrical energy is provided.

![Figure 5: Crack tip temperature.](image)

![Figure 6: Temperature contour.](image)

In Fig. 7, the electric current density near the crack tip at \( t = 0.06 \) s is plotted. Due to the opening condition of the crack, the electric current density vectors can not pass through the crack surfaces. It is noted that there is a field concentration at the crack tip. Similar to the elastic stress field, the electric current density also has the \( r^{-1/2} \) singularity at the crack tip. Under the Joule heating effect, this current density concentration induces the hot spot around the crack tip (Fig. 6).
4.2. Crack contact and crack welding

To achieve the crack welding, the compressive force $F_0$ must be used so that the crack surfaces can contact together. Then the electric current can pass through the crack and the Joule heating effect can induce a hot region along the crack.

The external loads $i_0=25000$ A and $F_0=5500$ N are applied on the plate boundary. The numerical result in Fig. 8 shows the temperature field and melted region (red color area). In Fig. 9, the electric current density vectors can pass through the crack. Due to the remote compressive load, the crack faces contact to each other. Similar to the resistance spot welding process, the crack surfaces can melt and weld together.

If the constant $\eta_{cel}$ is used in the analysis, the result in Fig. 10 is obtained. Comparing Fig. 8 and 10, these two results are different. The result of Fig. 8 is more practical because the electrical contact conductance is pressure-dependent and temperature-dependent.
5. CONCLUSIONS

To achieve the crack welding, the compressive force must be used so that the crack surfaces can contact together. Also, the contact pressure effect (pressure-dependent and temperature-dependent $\eta_{cel}$) must be considered in the finite element analysis to obtain more practical results.
