Abstract Polyfluoroalkyl anions, generated by reduction of (polyfluoroalkanoyl)piperidines with Et₃BH, were used for the polyfluoroalkylation of carbonyl compounds. Trifluoromethylation of aromatic aldehydes proceeded in good yields, and that of aliphatic aldehydes afforded a moderate yield. In contrast, the yield was low when the reaction involved benzophenone. Pentfluoroethylation and octafluorobutylatation of aldehydes were also carried out by using the corresponding (polyfluoroalkanoyl)piperidines, which were prepared from commercially available polyfluorocompounds. The (polyfluoroalkanoyl)piperidines were also prepared through polyfluorination, and were used in the polyfluoroalkylation of aldehydes.

INTRODUCTION

Nucleophilic trifluoromethylation of carbonyl compounds has been widely performed to introduce a trifluoromethyl group into the substrate.¹ The trifluoromethyl anion is unstable. Therefore, it is generated from the precursor in the presence of an electrophile such as a carbonyl compound. Although a number of various trifluoromethyl compounds have been used as precursors, trifluoromethyltrimethylsilane has been most frequently used and is well-studied.¹c,¹d,² Recently, trifluoroacetaldehyde hemiaminals (1) have attracted much attention as an accessible trifluoromethyl source, because they can be prepared from economical materials such as fluoroform³,³ and trifluoroacetaldehyde hemiacetal.¹¹,⁴ They are converted to their metal salts (2) to generate the trifluoromethyl anion.⁵ We can obtain 2 by the reduction of trifluoroacetamide (3).⁶ Moreover, various (polyfluoroalkanoyl)amides are obtainable from either commercially available
polyfluoroalkyl anions (Scheme 1).

**RESULTS AND DISCUSSION**

Trifluoromethylation of benzaldehyde was carried out using \(N\)-(trifluoroacetyl)piperidine, \(N\)-(trifluoroacetyl)pyrrolidine, and \(N,N\)-diethyl trifluoroacetamide as trifluoromethyl anion sources, and potassium triethylborohydride, DIBAH and potassium triisopropoxyborohydride as reducing reagents under various conditions (Table 1). A reducing reagent and benzaldehyde were successively added to the amide in THF at -78 °C (Entries 1–5) or at room temperature (Entry 6), and the resulting mixture was stirred for 24 h at 50 °C. Maintaining an interval between each addition of the reagents did not improve the results. The expected trifluoromethylated product (2a) was formed, only when \(N\)-(trifluoroacetyl)piperidine or \(N\)-(trifluoroacetyl)pyrrolidine was treated with potassium triethylborohydride (Entries 1, 4, and 6). The best yield was obtained by adding potassium triethylborohydride and benzaldehyde to \(N\)-(trifluoroacetyl)piperidine at room temperature (Entry 6).
The present trifluoromethylation reaction was applied to various carbonyl compounds. In the reaction with aromatic aldehydes and cinnamaldehyde, the corresponding trifluoromethylated products were obtained in good yield (Entries 1-5 in Table 2). From adamantane-1-carbaldehyde that has no $\alpha$-proton, the trifluoromethylated product was obtained in 60% yield (Entry 6). In contrast, the reaction with cyclohexanecarbaldehyde that has $\alpha$-proton, afforded an aldol reaction product as the main product. However, when the reaction was carried out in CH$_2$Cl$_2$ instead of THF, the trifluoromethylated product was obtained in 45% yield (Entry 7). In the reaction with benzophenone, most of the starting material remained unchanged (Entry 8).

\textsuperscript{a} If otherwise not mentioned, the reaction was carried out in THF using 2 eq of KB\(\text{Et}_3\)H and amide to carbonyl compound. The reagents were mixed at room temperature and stirred at 50 °C for 24 h. \textsuperscript{b} Isolated yield base on carbonyl compound used. In parentheses, \textsuperscript{19}FNMR yield. \textsuperscript{c} CH\textsubscript{2}Cl\textsubscript{2} was used as solvent.
As various (polyfluoroalkanoyl)piperidines are obtainable from commercially available polyfluorocompounds, the present method is applicable to the various polyfluoroalkylation of carbonyl compounds. For example, \( N \)-\( (\text{pentafluoropropanoyl}) \)piperidine (1b) was prepared from methyl pentafluoropropionate\(^7\) and was used for the pentafluoroethylation of 1-naphthaldehyde. The reaction proceeded similar to trifluoromethylation, and the pentafluoroethylated product (2i) was obtained in high yield. \( N \)-(2,2,3,3,4,4,5,5-\text{Octafluoropetanoyl})piperidine (1c) was prepared from commercially available 2,2,3,3,4,4,5,5-octafluoropentanol in three steps\(^7\)\(^-\)\(^9\) and was used in the reaction with 1-naphthaldehyde. The reaction of 1c with aldehyde was sluggish and the octafluorobutylated product 2j was formed in poor yield under the trifluoromethylation conditions. However, 2j was obtained in 61% yield by carrying the reaction at 40 °C for 24h using 4 equivalents of 1c and KBEt\(_3\)H to 1-naphthaldehyde without solvent (Scheme 2).

(Polyfluoroalkanoyl)piperidines can be also prepared through polyfluorination reactions. For example, methyl 2-(arylsulfanyl)-2,2-difluoroacetate (3) was prepared by difluorination of methyl 2-(arylsulfanyl)acetate using \( \text{IF}_3\)-Et\(_3\)N-3HF\(^{10}\) and then converted to \( N \)-2-(arylsulfanyl)-2,2-difluoroacetylpiperidine (4).\(^7\) The reaction of 4 with an aldehyde was performed as in the case of 2a, and the (arylsulfanyl)difluoromethylated product (5) was obtained in high yield (Scheme 3).
Methyl 2,2,3,3-tetrafluoro-3-phenylpropionate (7) was prepared from methyl 2-(arylsulfanyl)propionate in 74% yield by using our recently developed method, and the resulting 7 was converted to the amide (8). Although the reaction of 8 with aldehyde was sluggish, the expected polyfluoroalkylated product (9) was obtained in 60% yield by performing the reaction at 40 °C for 24 h using 4 equivalents of 8 and KEt₃BH to the aldehyde (Scheme 4).

**EXPERIMENTAL**

4.1. General

The melting points were measured with a Yanagimoto micro melting-point apparatus. The IR spectra were recorded using a JASCO FT/IR-410. The ¹H NMR (400 MHz) spectra, ¹⁹F NMR (376 MHz) spectra, and ¹³C NMR (100 MHz) were recorded in CDCl₃ on a JEOL JNM-A400II FT NMR and the chemical
shift, \( \delta \), is referred to TMS (\( ^1\)H, \( ^{13}\)C) and CFCl\(_3\) (\( ^{19}\)F), respectively. The EI-high-resolution mass spectra were measured on a JEOL JMS-700TZ. KBE\(_3\)H (1.0 M in THF) was purchased from Aldrich Chemica and KB(OPr\(^i\))\(_3\)H was prepared from B(OPr\(^i\))\(_3\) and KH according to the literature.\(^{12}\) IF\(_3\) in a stainless-steel cylinder was supplied by Asahi Glass Co., Ltd. IF\(_3\) was transferred through a Teflon™ tube into a Teflon™FEP bottle from the cylinder under an N\(_2\) atmosphere. IF\(_3\) was transferred quickly from the bottle to the reaction vessel made of Teflon™ FEP in open air. IF\(_3\) decomposes in air emitting HF fume, and, therefore, it should be carefully handled in a bench hood with rubber-gloved hands.\(^{11}\)

4,2,9. 2,2,3,3,4,5,5-Octafluoro-1-(naphthalen-1-yl)pentan-1-ol (2j)

To 1c (626 mg, 2 mmol) were added a 1.0 M THF solution of Et$_3$BHK (2 mL, 2 mmol) and 1-naphthaldehyde (78 mg, 0.5 mmol) successively at room temperature under N$_2$ atmosphere. Then a volatile part was removed under reduced pressure, and the resulting viscous mixture was stirred at 40 °C for 24 h. Then, 30% aqueous H$_2$O$_2$ (2 mL) was added at 0 °C, and after stirring for 1 h, the mixture was extracted with ether (30 mL X 3). The combined organic phase was dried over MgSO$_4$ and 2j was isolated by column chromatography (silica gel/CH$_2$Cl$_2$:hexane = 1:4) in 61% yield. White solid. Mp 75-77 °C.
