Abstract  Calamagrostis neglecta (Ehrh.) P. Gaertn., B. Mey. & Schreb. was observed growing on exposed sandy ground in Serebryanoye Mire on Kunashir Island in the southern Kuril Islands in 2012. The observation is noteworthy because C. neglecta typically grows in bogs and not in sandy environments. However, the high frequency of fog in the Yuzhno-Kuril’sk area is considered to supply the plant with sufficient water to support growth in sandy environments.

Key words: bog, Calamagrostis, Island, Kunashir, mire, Poaceae

Introduction

Calamagrostis neglecta (Ehrh.) P. Gaertn., B. Mey. & Scherb., a member of the family Poaceae, is distributed mainly in the bogs of the tundra regions in the northern hemisphere (Probatova 2003). In Japan, it is distributed mainly in eastern Hokkaido (e.g. Kushiro Mire and Bekanbeushi Mire), in bogs around lakes near Shiretoko, in northern Hokkaido (e.g. Sarobetsu Mire and Uryunuma Mire), and in Ozegahara in Honshu. Many of the bogs in which C. neglecta typically grows have a high conservation status in Japan due to their unique biological diversity. Calamagrostis neglecta is also distributed on Kunashir Island in the Kuril Islands, and one of the regions where it occurs is Lake Serebryanoye near Yuzhno-Kuril’sk City. Mires extend in the vicinity of Lake Serebryanoye and we have named the mire near the lake, Serebryanoye Mire (Furukamappu-Mire). Although C. neglecta is usually associated with bog environments (Osada 1989), the author has confirmed C. neglecta growing on sandy ground adjacent to Serebryanoye Mire. This report describes C. neglecta in this sandy environment.

Calamagrostis neglecta in Serebryanoye Mire

The author conducted a botanical survey of Serebryanoye Mire on 23 in August 2012. In this study, the name C. neglecta was used as C. inexpansa is the synonym of C. neglecta.

The author found C. neglecta growing on sandy ground beneath a power-transmission line in Serebryanoye Mire (Figs. 1, 2). The bog below the line was drained and denuded of vegetation due to construction of the line (Fig. 3). Rubus phoenicolasius Maxim., Artemisia montana (Nakai) Pamp., and Maianthemum dilatatum (A.W. Wood) A. Nelson et J.F. Macbr. were observed growing on the bare ground, but not in the bog (Fig. 4). Calamagrostis neglecta typically grows in bogs and it was unusual to find C. neglecta growing in sandy ground.

Specific growth environment

Calamagrostis neglecta does not typically grow on dry sandy ground. The surface of the ground was dry and growth conditions appeared unsuitable for this species. A burrow of what appeared to be a small mammal was situated near the observed C. neglecta plants (Fig. 5) and inside of the burrow was moist, not so dried. The author wondered where C. neglecta obtained sufficient water to survive in such an environment.

Mist occurs frequently near Yuzhno-Kuril’sk, and it is possible that this mist provided enough moisture for C. neglecta to grow on sandy soil (Fig. 6). According to Russians who accompanied us, fog occurs frequently on the Pacific Ocean-side of Kunashir, but it is usually fine on the Sea of Okhotsk-side. When we observed the island from a ship, we observed sea fog approaching the island from the Pacific Ocean-side of Kunashir (Fig. 7).

Bogs are oligotrophic wetlands that are not supplied with groundwater, and which remain moist due to water inputs from fog and rain. In this study, the bare sandy ground near the transmission lines was oligotrophic, which is similar to a bog. Sufficient moisture is supplied from the fog which likely infiltrates the bare ground at the site and supports the growth of C. neglecta on bare sandy ground.

Acknowledgements

We thank M. A. Antipin, I. G. Boyer, A. Budaev, A. Loguntsev and I. A. Nevedomskaya of the State Natural Reserve “Kurilskiy” for their assistance with our expedition. This study was supported in part by a Grant-in-Aid No. 21405009 to H. Takahashi for Scientific Research (B) from the Japan Society for the Promotion of Science.

佐藤広行：国後島古釜布湿原における砂地に生育するイネ科チシマガリヤスについて

国後島の古釜布湿原において、チシマガリヤスが砂地に生育しているのを確認した。チシマガリヤスは本来高層湿原に生育する植物であり、砂地には生育しない。チシマガリヤスを確認した場所は、本来は高層湿原であったが、送電線の建設のため植生が破壊され裸地になった場所である。砂地表面は乾燥していると思われたが、古釜布地域は霧が多く、チシマガリヤスが生育するのに十分な水分が霧から供給されていることが推察された。
