A Synthesis of Arylboronates via the Palladium(0)-Catalyzed Cross-Coupling Reaction of
Tetrakis(alkoxo)diborons with Aryl Triflates

Abstract: Tetrakis(alkoxo)diborons cross-coupled with aryl triflates at 80 °C in the
presence of PdCl2(dppf)-dppf catalyst and KOAc in dioxane, producing arylboronates in
excellent yields. The synthetic utility of the method was demonstrated by the tandem
coupling between two non-identical aryl triflates to give unsymmetrical biaryls.

Recent studies on the transformations of tetrakis(alkoxo)diborons1 (1) by
transition-metal catalysis provide new methodology for the synthesis of organoboron
compounds. The addition of 1 to alkynes,2 1,3-dienes,3 and alkenes4 is effectively
catalyzed by Pt(0), Rh(1), or Au(I) complex to provide a convenient access to stereodefined
bis(boryl)alkenes, bis(allyl)boronates, and bis(boryl)alkanes. The mechanism was
postulated to proceed through the oxidative addition of 1 to the low-valent metal complex
to form bis(boryl)metal intermediate. Alternative route from 1 to organoboron compounds
is the Pd(0)-catalyzed cross-coupling with organic electrophiles, which involves the
transmetalation of boryl group from 1 to R-Pd(II)-X intermediate. Haloarenes5 and allyl
acetates6 smoothly coupled with 1 in the presence or absence of base to afford the
corresponding aryl- and allylboronates. As a part of our program on the direct borylation
of organic electrophiles using 1, we wish to report here the Pd(0)-catalyzed cross-coupling
reaction of 1 with aryl triflates (2) to give arylboronates (3) (Eq. 1).
Initially, we examined the reaction between bis(pinacolato)diboron 1a (1.1 mmol) and 2 (1.0 mmol) under the conditions utilized in the similar coupling with haloarenes. Although phenyl triflate smoothly underwent the coupling at 80°C in the presence of PdCl2(dppf) catalyst (3 mol%) and KOAc (3 mmol) in DMSO (6 ml) to give a 91% yield of phenylboronate, relatively low yields were obtained when using substituted 2. The coupling of 2 having electron-withdrawing groups such as 4-acetylphenyl triflate was complete within 2 h under the conditions; however, it resulted only a 62% yield of 3 together with 4-hydroxyacetophenone (29%) caused by the base-promoted hydrolysis of 2. Electron-donating substituents extremely slowed down the reaction rate. The coupling of 4-methoxyphenyl triflate was incomplete even on prolonged heating (24 h), giving a 64% yield of 3 due to the catalyst decomposition. Presumably, dppf used as a ligand of palladium reacts with 2 to be converted into phosphonium salts.

Finally, the successfull coupling could be achieved in both cases by the use of dioxane as a solvent and the addition of dppf ligand (3 mol%). When the reactions of 4-acetyl- and 4-methoxyphenyl triflate were conducted under such conditions, the yields of 3 were improved to 92% (6 h) and 93% (13 h), respectively. Less polar solvent is favorable to avoid the hydrolysis of 2, but the use of toluene sufficiently slowed the coupling rate. The addition of LiCl, which is known to suppress the decomposition of catalyst in the Pd(0)-catalyzed cross-coupling of 2 with organostannanes, was totally ineffective in the present reaction. Although we have not investigated the effect of base, KOAc can be the most suitable base because stronger bases such as K3PO4 and K2CO3 may promote the further coupling of 3 with 2 leading to biaryls as reported in the similar reaction with haloarenes.

The procedure could be applied for other alkoxy derivatives of 1. The coupling of tetrakis(methoxy)diboron (1b) with phenyl triflate in the presence of PdCl2(dppf)-dppf catalyst and KOAc in dioxane for 6 h gave an 83% yield of 3 along with biphenyl (14%). For convenience of the analyses, the products were converted into the corresponding pinacol ester 3 (Eq. 2). On the other hand, the reaction of tetrakis(dimethylamido)diboron (4) was relatively slow resulting a 48% yield of 3.
The representative results of the cross-coupling reaction of 1a with various 2 are summarized in Table 1. 2 including a variety of electron-withdrawing and -donating substituents can participate in the present coupling to provide 3 in excellent yields. Strong electron-withdrawing property of nitro group was anticipated to enhance the hydrolysis of 2, but the exclusive formation of 3 was observed without such side reaction (Entry 1). ortho-Substituted 3 were also obtained by the reaction with the corresponding 2 (Entries 8 and 9), while all attempts at the coupling of more sterically hindered ortho-disubstituted 2 such as mesityl triflate were unsuccessful. Synthesis of 2 using Grignard or lithium reagents require the protection of functional groups sensitive to these reagents, but the present method is tolerated by various functional groups, e.g., CN, CHO, COMe, and CO2Me (Entries 2-5). Although the coupling of 8-quinolyl triflate satisfactorily gave the corresponding heteroarylboronates 3 (Entry 11), the similar reaction of 2-quinolyl triflate only gave quinoline resulted by the protodeboration of 3.11

The Pd(0)-catalyzed cross-coupling reaction of arylboron reagents with aryl electrophiles provides a promising route to construct aryl-aryl linkage, which is frequently observed in natural products, pharmaceuticals, and functional polymers. Thus, we applied the present method to one-pot synthesis of unsymmetrical biaryl (5) by a tandem cross-coupling reaction between two non-identical 2 (Eq. 3). When 4-acetylphenylboronate generated by the reaction of 1a (1.1 mmol) with corresponding 2 (1.1 mmol) was directly subjected to the next coupling with 4-cyanophenyl triflate (1.0 mmol) in the presence of K3PO4 (3 mmol) and additional PdCl2(dppf) catalyst (3 mol%) at 80 °C for 16 h, the desired 4-(4-acetyphenyl)benzonitrile was produced in 93% yield. The addition of the catalyst was indispensable to achieve high yield because of the catalyst decomposition during the first coupling. Similar tandem coupling between 4-methoxy- and 4-cyanophenyl triflate also afforded an 81% yields of 5. The reaction between 4-methoxy- and 4-methylthiophenyl triflate did not give good result under the conditions (less than 10%), but a 65% yield was achieved by the addition of dppf ligand (3 mol%).

Borylation of 2 (1.1 mmol) was carried out at 80 °C for 7-18 h by using 1a (1.1 mmol), PdCl₂(dppf) (3 mol%), dpff (3 mol%), and KOAc (3 mmol) in dioxane (6 ml) was followed by the next coupling with another 2 (1.0 mmol) at 80 °C in the presence of K₃PO₄ (3 mmol) and additional catalyst (3 mol%). *Isolated yields based on 2 employed at the second coupling.
