Reexamination of N composition dependence of coherently grown GaNAs band gap energy with high-resolution x-ray diffraction mapping measurements

Katsuhiro Uesugi, Nobuki Morooka, and Ikuo Suemune
Research Institute for Electronic Science, Hokkaido University, Sapporo 060-0812, Japan

(Received 30 March 1998; accepted for publication 29 December 1998)

GaNAs films grown on GaAs(001) substrates by metalorganic molecular beam epitaxy were studied by high-resolution x-ray diffraction (XRD) mapping measurements. The lattice constants of epitaxial films are usually estimated from symmetric and asymmetric XRD $2\theta-\theta$ measurements. In this study, it is pointed out that the consideration of the tilt angle between the GaAs(115) and GaNAs(115) planes caused by elastic deformation of the films is crucial to determine the lattice constants of the GaNAs films coherently grown on GaAs substrates. Mapping measurements of (115) XRD $(2\theta-\theta) - \Delta \omega$ were performed for this purpose. The band gap energy of the films was determined by Fourier transform absorption spectroscopy measurements. The band gap energy bowing measured up to the N composition of 4.5\% will be discussed by comparing with other measurements and theoretical calculations. © 1999 American Institute of Physics.

GaNAs alloys have been intensively investigated to fabricate new III-V light emitting devices for optical communications. They have peculiar properties compared with conventional III-V alloys, such as large redshift of band gap energy with increasing N compositions. Weyers, Sato, and Ando\textsuperscript{1} and Kondow \textit{et al.}\textsuperscript{2} experimentally demonstrated the reduction of band gaps in diluted Ga$_{1-x}$As$_x$ alloys ($x<1.5\%$). GaNAs films were grown on a GaAs substrate by metalorganic chemical vapor deposition (MOCVD) and gas-source molecular beam epitaxy (GSMBE), respectively. The measured band gaps were very close to the one calculated by Sakai, Ueta, and Terauchi\textsuperscript{3} based on the dielectric model.\textsuperscript{4} Ougazzaden \textit{et al.} reported the GaNAs with 3\% N composition grown on a GaAs substrate using atmospheric pressure metalorganic vapor phase epitaxy (AP-MOVPE).\textsuperscript{5} They obtained a peak photoluminescence (PL) wavelength of 1.17 $\mu$m at room temperature. Bi and Tu recently reported the optical behavior of GaNAs films ($x\approx14.8\%$) grown on a GaP substrate by GSMBE.\textsuperscript{6} They showed that the band gap bowing was dependent on the N composition in GaNAs films. We have also reported similar band gap bowing of GaNAs films ($x\approx7.2\%$) grown on a GaAs substrate by metalorganic molecular beam epitaxy (MOMBE).\textsuperscript{7}

More recently, Bellaiche, Wei, and Zunger demonstrated the dependence of the calculated band gap of GaNAs on the crystalline structures, such as bulk and coherently strained conditions.\textsuperscript{8} They showed the importance of lattice relaxation, chemical effects, and disorder on the band gap of GaNAs. Therefore, it is important to study the detailed strain properties of the GaNAs films. In this study, high-resolution X-ray diffraction (XRD) mapping measurements\textsuperscript{9,10} were carried out to determine the strain properties of the epitaxial GaNAs films and the N composition in GaNAs. Precise lattice structures of the epitaxial films were extracted from (004) $2\theta-\theta$ scan and two-dimensional $(2\theta-\theta) - \Delta \omega$ mapping around (115) diffraction peaks as described below. We will discuss the comparison between the measured band gap bowing of the coherently strained GaNAs on (001) GaAs and the previous reports.

GaNAs films were grown on semi-insulating GaAs(001) substrates by MOMBE. The precursors used were triethylgallium, monomethylhydrazine, and trisdimethylaminoarsenic. GaNAs films 0.1–1 $\mu$m thick were grown at temperatures of 520–570 °C. Detailed growth conditions are reported elsewhere.\textsuperscript{7,11} The XRD analyses were carried out using a Philips high-resolution XRD system. For the collimator in front of the detector, a Ge(220) analyzer was used.

In order to determine the lattice parameter of the epitaxial films perpendicular ($a_\perp$) and parallel ($a_\parallel$) to the (001) substrate surface, both symmetric and asymmetric reflections are usually measured by the conventional $2\theta-\theta$ scan method.\textsuperscript{12–14} Figure 1 shows a typical (004) $2\theta-\theta$ curve of a GaNAs film (optimization of $2\theta-\theta$ scan is done for the Bragg peak of the GaAs substrate as a reference crystal). A GaNAs peak and some thickness fringe peaks are clearly observed. This suggests that the solid composition is

![FIG. 1. Typical (004) $2\theta-\theta$ curve of the GaNAs film grown on the GaAs substrate. The full width at half maximum of the GaAs peak and the GaNAs peak is 17 and 47 arc sec, respectively.](Image)
homogeneous and the film has a high epitaxial quality. The film tilt between the GaAs(001) and the GaNAs(001) planes was not observed by the (004) measurement of this sample rotated 180° around the surface normal. From the separation between the GaAs and GaNAs peaks, \( a_\parallel \) is estimated to be 5.6356 Å. The thickness of the GaNAs film is calculated to be 0.37 μm by the usual formula.

It is well known that the inclination between the asymmetric plane of the substrate and that of the epitaxial film is usually observed if the film is subject to a tetragonal distortion. The angle \( \psi \) between the (001) plane and the (115) plane of the strained films is estimated from \( \psi = \tan^{-1}(\sqrt{2}a_\parallel /5a_\parallel) \). When the lattice structure has the cubic symmetry such as the GaAs substrates or lattice matched or fully relaxed epitaxial films (\( a_\parallel = a_\perp \)), \( \psi \) is the constant value of 15.793°. However, \( \psi \) for the epitaxial films under the elastic distortion is dependent on the lattice parameters \( a_\parallel \) and \( a_\perp \), which suggests that \( \psi \) is generally dependent on the strain in the grown epitaxial film. The tilt angle \( \Delta \psi \) between the GaAs(115) plane and the GaNAs(115) plane is related through the equation

\[
\Delta \psi = \tan^{-1}(\sqrt{2}/5) - \tan^{-1}(\sqrt{2}a_\parallel /5a_\parallel).
\]

Since the conventional \( 2\theta - \theta \) scan can measure only in one of the [115] directions of either the substrate or the strained film, a single scan cannot determine the diffraction angle with enough accuracy. \( \Delta \psi \) is usually estimated by the two \( 2\theta - \theta \) curves with the sample rotated by 180° around the (115) plane normal. In this study, high resolution \( 2\theta - \theta \) - \( \Delta \omega \) mapping methods were used as the characterization technique to determine both the tilt angle \( \Delta \psi \) and the actual Bragg angle of the film. The mosaic structure of the films was also observed.

Figure 2 shows a typical \( 2\theta - \theta \) - \( \Delta \omega \) map around the (115) diffraction peaks. This map was constructed by the repeated \( 2\theta - \theta \) scans at the different offsets to \( \theta (\Delta \omega) \). It can be seen that the diffraction peaks from the GaAs(115) and GaNAs(115) planes are directly observed on the map. The separation of the GaNAs peak in the offset \( \Delta \omega \) is estimated to be 0.048°, which corresponds to the tilt angle \( \Delta \psi \) between the GaNAs(115) and GaAs(115) planes. From the Bragg angle of the GaNAs(115) plane in Fig. 2, the \( d \) spacing of the GaNAs(115) plane \( d_{115} \) is estimated to be 1.0848 Å. The lattice parameter parallel to the (001) surface \( a_\parallel \) is related to the above-determined quantities \( (a_\perp, \Delta \psi \text{ and } d_{115}) \) by the equation

\[
1/d_{115}^2 = 2/a_\parallel^2 + 25/a_\parallel^2 \quad (2)
\]

and Eq. (1). From these equations, \( a_\parallel \) is calculated to be 5.653 Å, which is in good agreement with the lattice constant of GaAs \( (a_{GaAs}) \). This shows that the GaNAs film was coherently grown on the GaAs surface. These results show that the asymmetric XRD mapping measurements can precisely determine the three-dimensional crystalline structures of the coherently grown epitaxial films.

The elastic deformation of the epitaxial films is expressed by

\[
a_\perp = a_\parallel + (C_{11} + 2C_{12})/(C_{11})(a_0 - a_\parallel),
\]

where \( C_{11} \) and \( C_{12} \) are the elastic constants for GaNAs and \( a_0 \) is the lattice constant of cubic GaNAs. The N composition \( x \) is estimated from \( a_0 \) assuming Vegard’s law

\[
a_0 = xa_{GaN} + (1 - x)a_{GaAs},
\]

where \( a_{GaN} \) is the lattice constant of cubic GaN (4.50 Å). Since the elastic constants for GaNAs are not available, linear interpolation was used for GaAs and cubic phase GaN. As for the possible bowing of the GaNAs elastic constants, the maximum error for the 5% N composition was estimated by assuming the extreme cases of GaAs and GaN elastic constants, which were 5.06% and 4.52%, respectively. The N composition determined in this way showed good agreements with other data confirmed by the secondary ion mass spectroscopy (SIMS), which will be shown in Fig. 4 later.

Figure 3(a) summarizes the measured lattice parameters of the GaNAs films. The solid and dashed lines are the calculated lattice parameters perpendicular \( (a_\perp) \) and parallel \( (a_\parallel) \) to the GaAs substrate surface of coherently strained GaNAs. Figure 3(b) shows the corresponding dependence of \( \Delta \psi \) on the N composition measured by (115) XRD maps.
The solid and dashed lines are calculated from Eq. (1) for coherently strained \( a_i = a_{\text{GaAs}} \) and fully relaxed \( a_i = a_i \) GaNAs geometries, respectively. The measured results are in good agreement with the calculations, and this shows that all the samples are coherently grown on the GaAs(001) substrates.

The band gap energy of GaNAs films was estimated by Fourier transform absorption spectroscopy measurements at 300 K. The N composition dependence of the measured band gap energies is shown in Fig. 4 by the closed circles. All the GaNAs films are coherently grown on (001) GaAs as discussed above. The dashed lines are the theoretical band gap energies, based on the dielectric model and on the first-principle supercell models by Bellaiche et al. (Ref. 8).
