1 Abstract

 $\mathbf{2}$ Endo-β-1,4-mannanases from *Streptomyces thermolilacinus* (StMan) and Thermobifida fusca (TfMan) showed different substrate specificities. StMan hydrolyzed 3 galactosylmannooligosaccharide (GGM5; 6^{III},6^{IV}-α-D-galactosyl mannopentaose) to 4 GGM3 and M2 while TfMan hydrolyzed GGM5 to GGM4 and M1. To determine the $\mathbf{5}$ 6 region involved in the substrate specificity, we constructed chimeric enzymes of StMan $\mathbf{7}$ and TfMan and evaluated their substrate specificities. Moreover, the crystal structure of the catalytic domain of StMan (StMandC) and the complex structure of the inactive 8 mutant StE273AdC with M6 were solved at 1.60 and 1.50 Å resolution, respectively. 9 Structural comparisons of StMandC and TfMandC lead to the identification of a subsite 10around -1 in StMandC which could accommodate a galactose branch. These findings 11 demonstrate that the two loops (loop7 and loop8) are responsible for substrate 12recognition in GH5 actinomycete mannanases. In particular, Trp281 in loop7 of StMan, 13which is located in a narrow and deep cleft, plays an important role in its affinity toward 14linear substrates. Asp310 in loop8 of StMan specifically bound to the galactosyl unit in 15the -1 subsite. 16

1 Introduction

 $\mathbf{2}$ Plant biomass is an abundant carbon source and important sustainable biomaterial. The plant cell wall comprises cellulose, hemicelluloses, and lignin. Microbial enzymatic 3 4 degradation is a key requirement for the involvement of the carbon cycle in the utilization of hard biomass [1-3]. Cellulose, a β -1,4-linked glucose polymer, can be $\mathbf{5}$ 6 converted to bioenergy [4]. Hemicellulose, a polymer composed of various types of sugars, also has the potential to be a sustainable biomaterial for bioenergy and bioactive 7compounds [5-7]. Mannan is one of the major hemicellulose components that exist as 8 glucomannan or galactomannan in softwood or bean seeds [8]. Mannan consists of 9 β -1,4-linked mannose polymers which are decorated with α -1,6-linked galactose 1011 branches. The amount of branched chains is dependent on the species and is also related 12to the physical properties of mannan [9-11].

For the deconstruction of mannan, cooperative degradation via a series of 13glycoside hydrolases [e.g., β-1,4-mannanase (EC 3.2.1.78), β-1,4-mannosidase (EC 14**3.2.1.25**), α -galactosidase (EC 3.2.1.22)] and accessory enzymes (e.g., carbohydrate 15esterases) are necessary [12-14]. Mannanases, a major enzyme group used for mannan 16degradation, has been classified into three groups, glycoside hydrolase family (GH) 5, 26, 17and 113 (http://www.cazy.org/). Among these groups, GH5 mannanase is considered to 1819primarily function in hemicellulose deconstruction because most GH5 mannanases are extracellular hydrolases and have carbohydrate binding modules (CBMs) [15, 16]. CBMs 2021usually bind to insoluble or soluble saccharides with various conformations via a linker domain to increase the catalytic efficiency of the enzymes [17]. Recently, accessory 22enzymes with CBMs have been speculated to be involved in the cooperative 2324deconstruction of the plant cell wall [18, 19]. The molecular architecture of most GH26 25mannanases consists of only a catalytic domain which cannot hydrolyze mannan in the plant cell wall, while some GH26 mannanases with CBMs do exhibit hydrolysis activity 2627toward mannan [20], suggesting that target saccharides are differentiated by mannanases depending on whether they have CBMs or not [21]. Therefore, the analysis of the 28

molecular architecture of these enzymes is important for improving our understanding of the deconstruction of hemicellulose. The degradation of linear saccharides by catalytic domains has been extensively studied [22-25]. Some GH5 mannanases exhibit high activity toward short substrates [26-28]. Specificity toward branched mannan has been studied in *Streptomyces* sp. SirexAA-E mannanase [29]. However, it is still unclear how the catalytic domains of these enzymes recognize and degrade linear or branched mannan structures.

We have studied the relationship between the structure and function of GH5 8 actinomycete mannanases [30-33]. The end-products of locust bean gum (LBG: 9 galactosyl mannan) degraded by a catalytic domain of mannanase from Streptomyces 1011 thermolilacinus (StMandC) were mainly M2 and M3, while that from Thermobifida fusca (TfMandC) were mainly M1, and M2 [33]. Mannanase activity toward mannan 12usually decreases as the degree of modification of branched chain galactoses increases. 1314Understanding the mechanism of mannanase catalysis of galactosyl-mannan should provide further insight into mannan degradation, and improve the use of an optimal 15combination of mannanase and other hydrolases or accessory enzymes for mannan 16degradation. 17

In this study, by using linear mannooligosaccharides and branched galactosyl 18 19mannooligosaccharide, we investigated the substrate specificities of StMandC and TfMandC. Moreover, we investigated the role of two loops (loop7 and loop8) in their 2021substrate specificity toward linear mannooligosaccharides and branched galactosyl mannooligosaccharides (GGM5) by using StMan, TfMan, their chimeric enzymes, and 2223mutants. To confirm the kinetic results, we solved the crystal structure of StMandC and a 24complex structure of the inactive mutant StE273AdC with M6. Our data demonstrated 25the relationship between the structure and substrate specificity of GH5 actinomycete mannanases. 26

27

28 **Results**

1 Identification of the region involved in substrate specificity

 $\mathbf{2}$ When StMandC hydrolyzed GGM5, two peaks were detected by HPAEC-PAD analysis. One peak was determined to be mannobiose (M2) and the remaining 3 4 degradation product was identified as GGM3 (Fig. 1A and B). However, when TfMandC hydrolyzed GGM5, mannose (M1) was detected (Fig. 1B). Mannose residues at the $\mathbf{5}$ 6 reducing and non-reducing termini were present in GGM5. Using a labelling agent (ABEE), we modified the reducing terminus of the sugar to evaluate the mannanase 7hydrolysis pattern of GGM5. The hydrolysis product of GGM5-ABEE by TfMandC was 8 M1-ABEE, indicating that TfMandC hydrolyzed the reducing terminus of GGM5 (Fig. 9 1C). 10

Four chimeric mannanases (STMan3dC consisting of residues 36-246 of StMan 11 12and 227-330 of TfMan, STMan4dC consisting of 36-260 of StMan and 250-330 of TfMan, STMan5dC consisting of 36-308 of StMan and 288-330 of TfMan, and 1314TSMan3dC consisting of 29-226 of TfMan and 247-349 of StMan) were constructed to evaluate the GGM5 hydrolysis pattern (Fig. 2A). STMan3dC and STMan4dC 15hydrolyzed GGM5 to form GGM4 and M1 and TSMan3dC produced GGM3 and M2 (Fig. 163A). The C-terminal region (amino acid residues 258–349 in StMan) has been speculated 1718to determine the substrate specificity of StMan. STMan5dC was significantly less 19reactive toward GGM5 compared with the parent enzymes and the three other chimeric mutants (for example, GGM5 activity of StMandC and STMan5dC were 10.1 and 0.012 2021U/mg, respectively). STMan5dC exhibited the GGM5-cleavage reactions of two wild-type enzymes in terms of its GGM5 hydrolysis products (M1, M2, GGM3, and 2223GGM4), indicating that the GGM5 hydrolysis pattern could be determined by two regions: the amino acid sequences 258-302 and 303-349 of StMan (Figs. 2A and 3A). 2425The alignment of these regions of StMandC and TfMandC showed that both regions contain two single-loop-structures with low sequence identity [loop7: 276-283 2627(GPPDQWGD) for StMan and 256-262 (HDHSDGN) for TfMan; loop8: 309-312 (TDPV) for StMan and 288–293 (GGGVEY) for TfMan] (Fig. 2B). We then constructed 28

1 six substitution mutants, of which loop7 and loop8 of StMandC were replaced with those $\mathbf{2}$ of TfMandC and vice versa $(S(S-L7 \rightarrow T-L7)dC, S(S-L8 \rightarrow T-L8)dC, S(S-L7/L8 \rightarrow T-L8)dC)$ T-L7/L8)dC, T(T-L7 \rightarrow S-L7)dC, T(T-L8 \rightarrow S-L8)dC, and T(T-L7/L8 \rightarrow S-L7/L8)dC; see 3 4 Fig. 2C for construction of mutants), and evaluated the GGM5 hydrolysis patterns with these mutants. $S(S-L7 \rightarrow T-L7)dC$, $S(S-L7/L8 \rightarrow T-L7/L8)dC$, $T(T-L7 \rightarrow S-L7)dC$ could not $\mathbf{5}$ 6 hydrolyze GGM5. $S(S-L8 \rightarrow T-L8)dC$ and $T(T-L8 \rightarrow S-L8)dC$ hydrolyzed GGM5 with significantly lower activity to produce M1, M2, GGM3, and GGM4 (Fig. 3B). The 7GGM5 hydrolysis products of T(T-L7/L8 \rightarrow S-L7/L8)dC having loop7 and loop8 of 8 StMan were identical to those of StMan (Fig. 3B). Based on these results, we concluded 9 the substrate specificity of mannanases is determined by the two loop-structures. 10

11

12 Kinetic parameters of StMandC and TfMandC

Both of StMandC and TfMandC displayed no activity on M2 and drastically low 13activity on M3, making it impossible to determine the kinetic parameters for these two 1415substrates. Therefore, the kinetic parameters of mannanases toward mannooligosaccharides (M4, M5, and M6) and GGM5 are listed in Table 1. Among these 16substrates, both enzymes showed the highest activity toward M6. The k_{cat}/K_m values 17toward M5 and M4 of StMandC were approximately 10- and 100-fold lower than that of 18M6. The k_{cat}/K_m values toward M4 of TfMandC were approximately 100-fold lower than 19that of M5 and M6. The k_{cat}/K_m values of StMandC toward M4, M5, and M6 was 1.6-, 202113-, and 2.4-fold lower than those of TfMandC, respectively. In particular, TfMandC had 22a 13-fold higher k_{cat} value toward M5 than that of StMandC. However, both enzymes were the least active toward GGM5. The values of k_{cat}/K_m toward GGM5 were very low 2324compared with linear mannooligosaccharides. The k_{cat}/K_m and k_{cat} of StMandC toward 25GGM5 were 13- and 10-fold higher than those of TfMandC, respectively.

The crystal structures of StMandC and its inactive mutant, StE273AdC, with 1 $\mathbf{2}$ substrate were solved. The overall structure of StMandC revealed that the protein was 3 composed of a $(\beta/\alpha)_8$ -barrel fold similar to that of other GH5 mannaness belonging to 4 Clan GH-A (Fig. 4A). StMandC possessed calcium ion-binding site and one residue (Glu286) has been found as calcium ion-binding residue [31]. From crystal structure of $\mathbf{5}$ 6 StMandC, the side chain of Glu286 and Asp283, and main chain of Gly276 and Pro284 were involved in calcium ion-binding in loop7. The structure of StE273AdC in complex 7with substrate was successfully determined by soaking with M6 (Fig. 4A). The electron 8 density map of mannose residues was found at subsites -4 to +3 (Fig. 4B), indicating 9 various binding patterns of M6 to StE273AdC, since seven subsites (i.e., seven mannose 1011 units) were found by soaking with M6. The subsite -1 was occupied by two moieties of mannose, an internal moiety in the boat-form conformation B_{2,5} and a reducing-terminal 12moiety in the skew-boat conformation ${}^{1}S_{5}$, whose equatorial O1 was interacted with 13Tyr246 by a 2.72 Å hydrogen bond (Fig. 4C). These conformations represented one of 14the structures of the mannose chain [34]. The plus subsites in StMandC consisted of a 15hydrophobic cleft, Trp215 at subsite +1, Trp281 at subsite +2, and Trp219 at subsite +3. 16Gln217 in loop5 bound to the OH-C(3) of mannose at subsite +2 with a 2.84 Å hydrogen 17bond. Binding of OH-C(2) mannose was thought to play a key role in determining the 1819substrate specificity between mannanases and cellulases [22]. Trp219 and Asn182 bound to the OH-C(2) of mannose at subsite +2 with a 2.99 and 3.33 Å hydrogen bond, 2021respectively. These residues created a narrow and deep cleft at the plus subsite side. The crystal structure of StE273AdC complexed with substrate revealed that the cleft was 2223suitable for the incorporation of mannose residues containing a twisted glycoside linkage 24at subsites -1 and +1. The superimposed model of StMandC and StE273AdC showed 25that loop7 of StE273AdC shifted toward the substrate (Fig. 4A and B). Trp281 in loop7 moved into proximity to subsite +2 mannose, which would increase the interaction with 2627the substrate (Fig. 4D). Thus, we speculated that Trp281 in loop7 plays an important role in substrate recognition. 28

1 The superimposed model of StE273AdC with M6 and T. fusca KW3 mannanase $\mathbf{2}$ with M3 (PDB code: **3MAN**) showed that the mannose main chain was almost coincident at subsites -3 to -2, and the substrate-binding residues were well conserved, with the 3 4 exception of Val263 (3MAN) bound to mannose at subsite -1, which did not correspond to the StMandC residue (Fig. 5A) [22]. Thr309 in loop8 of StMan, equivalent to Gly260 $\mathbf{5}$ in 3MAN, was most likely involved in the binding of OH-C(6) mannose at subsite -3 6 (Fig. 5A). The plus subsites were compared with T. fusca KW3 mannanase (PDB code: 78 **1BQC**) because the structure of 3MAN was lacking loop7 (Fig. 5B). Amino acid residues in loop4 and loop5 comprising the plus subsites were conserved (Fig. 5B). However, 9 those of loop7 and loop8 comprising the opposite plus subsites were different: 1BQC had 10a wide cleft because of a short loop7 compared with that of StMandC, while Trp281 in 11 loop7 of StMan constituted a narrow and deep cleft with loo4 and loop5 (Fig. 6). 12Additionally, loop7 and loop8 in StMandC generated a space around subsite -1 (Fig. 6B). 13It was supposed that this space accommodated the galactose branch, resulting in the 14different GGM5 hydrolysis patterns. The crystal structure of StMandC revealed that 15Asp310 in loop8 binds to the galactose branch around the -1 subsite. 16

17

18 Amino acid residues related to the substrate specificity of mannanases

From the structure of StMandC, we speculated that Trp281 in loop7 and Asp310 in loop8 were a mannose-main-chain binding residue and galactose-branch-chain binding residue, respectively. We constructed alanine mutants of Trp281 (StW281AdC) and Asp310 (StD310AdC). The kinetic parameters for StW281AdC decreased for the substrates. Their k_{cat}/K_m toward linear mannooligosaccharides (M4–M6) was 7- to 2-fold lower than those of StMandC (Table 1). The k_{cat}/K_m of StD310AdC toward GGM5 decreased approximately 5-fold compared with that of StMandC (Table 1).

26

27 Discussion

28

Understanding enzymatic properties is essential for determining an enzyme's role

in nature. Herein, we found that the substrate specificity of two types of GH5
actinomycete mannanases were related to their loop structures. Namely, a combination of
loop7 and loop8 of StMandC is essential for accommodation of the galactose branch at
the -1 subsite, however the residues critical for determining the substrate specificity
were unclear.

6 The value of k_{cat} of StMandC toward GGM5 was the main factor determining the value of k_{cat}/K_m . The value of k_{cat} was $10^2 - 10^4$ -fold lower compared with those for the 7linear substrates. GGM5 is composed of a mannopentaose main chain with two galactose 8 branches, suggesting that the galactose branches affected the k_{cat} . The crystal structure of 9 GH5 endoglucanase and β -mannosidase revealed that the sugar at subsite -1 was 10distorted, and the glycoside linkage between subsites -1 and +1 was twisted [28, 35]. 11 The complex structure of GH26 mannanase with a mannooligosaccharide possessing a 12galactose branch at the -1 subsite indicated that the galactose residue affected the 13mannose chain at the +1 subsite [36]. The complex structure of StE273AdC also revealed 14that the glycoside linkage between subsites -1 and +1 was twisted. The distortion of the 15sugar at the -1 resulted in a decrease in the distance between the OH-C(6) mannose at 16subsite -1 and the OH-C(3) mannose at subsite +1 and a decrease in the catalytic 17efficiency toward GGM5. Asp310 in loop8, which could not bind to the mannose main 18chain, is located around the -1 subsite. The decrease in k_{cat}/K_m toward GGM5 was 19primarily related to the decrease in k_{cat} . This indicated that Asp310 may assist in the 2021distortion of the sugar at the -1 subsite by binding the galactose residue. Trp281 in loop7 22of StMandC created a narrow cleft at subsite +2, thereby allowing a mannose residue to 23bind with a twisted glycoside linkage between subsites -1 and +1. The parameter most 24affected by the mutation was the k_{cat} toward M4, indicating that Trp281 was an important 25residue for the catalytic activity toward the short substrate M4 (Table 1). It was thought that Trp281 was also necessary for distortion of the sugar at subsite -1. These results 2627suggest that Trp281 in loop7 is involved in the catalytic activity toward short linear substrates, while Asp310 in loop8 is specifically involved in the binding of branched 28

substrates. The hydrolysis patterns of GGM5 resulting from these mutants were similar
to that of StMan (i.e., GGM5 was hydrolyzed to GGM3 and M2) (data not shown). Thus,
other residues were also involved in determining the hydrolysis pattern of GGM5.

4 Streptomyces sp. SirexAA-E mannanase (SACTE_2347), which showed 79% identity with StMandC and possessed loops L1 and L2, corresponding to loop7 and loop8 $\mathbf{5}$ 6 of StMandC, respectively, hydrolyzed GGM5 to GGM3 and M2 [29]. The crystal structure of SACTE_2347 showed the space which could accommodate the galactose 7branched around the -1 subsite. Trp281 and Asp310 of StMan were equivalent to Tyr281 8 and Asp310 of SACTE 2347, respectively, implying that their possible functions are 9 short substrate-binding (Tyr281 of SACTE_2347) and distortion of the sugar at the -1 10subsite (Asp310 of SACTE_2347). Thr309 in loop8, which was conserved in both 11 12enzymes, might be the key residue to determine substrate specificity toward branched substrates by disturbing the accommodation of galactose branches around the -3 subsite. 13

The value of k_{cat}/K_m for TfMandC toward GGM5 decreased 10⁵-fold compared 14 with that for M5. For StMandC, the difference in k_{cat}/K_m between GGM5 and M5 was 1510³-fold. From analysis of the hydrolysis products of GGM5, it was determined that 16TfMandC could accommodate the galactose branches in the vicinity of subsites -3 and 17-2, while StMandC accommodated galactose branches around subsites -2 and -1. When 1819using M5 as a substrate, both TfMandC and StMandC remove M1 and M2 from M5 to a similar amount (Fig. 7). However, the two enzymes had different reactivities toward 2021GGM5 (Fig. 1). Therefore, the decrease in k_{cat}/K_m for TfMandC and StMandC toward GGM5 was related to the steric hindrance created by the accommodation of the galactose 2223branches. Around subsite -2, loop2 and loop3 could accommodate the galactose branch 24(Fig. 5). The putative galactose binding residues between StMandC and TfMandC appear 25to be conserved: Arg108 in loop2, and Thr139 and Asp144 in loop3 of StMandC correspond to Arg58 in loop2, Thr89 and Gln94 in loop3 of TfMandC. Around the -3 26subsite, the complex structure of StMandC with M6 showed a 2.7 Å hydrogen bond 27between Thr309 and the OH-C(6) of mannose at subsite -3. Therefore, Thr309 should 28

inhibit the accommodation of the galactose branch at the -3 subsite, leading to the 1 $\mathbf{2}$ substrate specificity of mannanases. At the -1 subsite, Val263 in loop8 of TfMandC 3 would fill the space [22] (Fig. 6C). Loop8 was necessary for the substrate specificity of 4 TfMan-type enzymes because the accommodation of a galactose branch at the -3 subsite would be attributed to loop8. We assumed that the substrate specificity of the loop8 $\mathbf{5}$ 6 substitution mutant $S(S-L8 \rightarrow T-L8)dC$ changed to a TfMandC-type, i.e., galactose branches were accommodated at subsites -3 and -2. However, $S(S-L8 \rightarrow T-L8)dC$ 7displayed less hydrolytic reaction: GGM5 to GGM4 and M1. Additionally, the loop8 8 substitution mutant T(T-L8 \rightarrow S-L8)dC also could not hydrolyze GGM5 to GGM3 and 9 M2, suggesting that loop7 contained important residues for substrate specificity. 1011 Therefore, we speculated that the difference in the accommodation of mannose residues 12at the plus subsites would be directly related to the enzyme's substrate specificity.

The synergistic degradation of hemicelluloses has been proposed to be carried out 13by GH5 and GH26 mannanases [21]. The genome of Actinomycete sp. contains both GH5 14and GH26 mannanase genes. Most GH5 mannanases in Actinomycetes have 15loop-structures similar to those of StMan or TfMan (Fig. 8). Interestingly, several species 16such as *Streptomyces coelicolor* A3(2) and *Streptomyces scabiei* 87.22 possess more than 17two kinds of GH5 mannanase genes similar to those of StMan and TfMan (Fig. 8). 1819SACTE_2347 was classified as a StMan-type enzyme, supporting the close relationship between the sequence alignment and the function of enzymes. The end-products from 2021LBG by these enzymes were mainly M2 [29, 33]. β-1,4-Mannosidases from GH1 and GH2 catalyzed further hydrolysis of M2, and some GH5 mannanases could hydrolyze 2223M2 [26, 27]. GH5 β-1,4-mannosidase from Actinomycete sp. has not been found, 24however it is possible to hydrolyze mannan to mannose by symbiotic degradation among 25GH5 mannanases. A combination of GH5 mannanases would have the potential to act synergistically to deconstruct lignocellulosic materials. 26

In conclusion, this study highlights the different enzyme properties of GH5 mannanases from *Actinomycetes* sp. Both loop7 and loop8 are key regions which

determine substrate specificity. StMan-loops can contribute to the hydrolysis of a
mannose chain decorated with a galactose branch around the -1 subsite, while
TfMan-loops show high activity toward linear mannan. The alignment shows that the
many characteristics of mannanases are conserved in *Actinomycetes* sp.

 $\mathbf{5}$

6 Materials and methods

7 Construction, expression, and purification of Actinomycete mannanases

8 To evaluate the region involved in mannanase substrate specificity, we used expression plasmids encoding the catalytic domains of StMan (StMandC) and TfMan 9 (TfMandC) and chimeric enzymes combining StMandC and TfMandC (STMan3dC and 1011 TSMan3dC) [30]. The other chimeric enzymes (STMan4dC and STMan5dC) were 12prepared using the Repeat-length-Independent Broad-Spectrum (RIBS) DNA shuffling method described in the following section. The recombinant proteins were expressed in 1314 Escherichia coli BL21-Gold (DE3) cells (Agilent Technologies, Palo Alto, CA, USA) harboring the pET28a construct (mannanase). The recombinant proteins were purified 15from cells as previously described [31] and concentrated using a 10,000-MW cutoff 16Amicon® ultra membrane (Millipore, Billerica, MA, USA) for use in subsequent 17experiments. The purities of the recombinant proteins were confirmed by using 1819SDS-PAGE [37]. The protein concentrations were determined by the Bradford method [38] using BSA as the standard. 20

21

22 Preparation of chimeric enzymes using the RIBS shuffling system

Chimeric enzymes were prepared using the RIBS *in vivo* DNA shuffling system, which is an improved method of chimera genesis based on highly frequent deletion formation using the *E. coli ssb*-3 strain [39]. The parental mannanase genes, gentamicin resistance gene (Gm^r) and *E. coli rpsL*⁺ gene [streptomycin-sensitive (Sm^s)], were tandemly cloned into the *NdeI-HindIII* sites of pET28a. The rank order of these genes was *stman*-Gm^r-*E.coli rpsL*⁺-*tfman*, and then *E. coli* MK1019 [*ssb*-3 *rpsL* (Sm^r)]

harboring pET28a (StMan/Gm^r-*rpsL*/TfMan) was obtained. Thirty transformants were 1 $\mathbf{2}$ cultured overnight in Luria Broth (LB) medium containing 50 µg/mL chloramphenicol and each culture was spread and then cultivated on LB plates containing 50 µg/mL 3 4 chloramphenicol and 50 µg/mL streptomycin. Plasmids containing chimeric mannanase (c-man) genes were isolated from 80 colonies. A total of 10 clones with different c-man $\mathbf{5}$ 6 genes were obtained. The catalytic domain of the enzymes was produced by PCR using a previously reported method [39]. Each chimeric construct was named based on 7recombination positions from the N-terminus of StMan. For example, chimera1-Man 8 (c1-man) was designated as ST-C85. Among the *c*-man genes, the catalytic domain 9 mutants of ST-C258dC and ST-C302dC, which were designated STMan4dC and 1011 STMan5dC, respectively were used in this study.

12

13 Preparation of mutant enzymes

To evaluate the effects of loop-structure on substrate specificity, we generated 14loop7 and loop8 substitution mutants (S(S-L7 \rightarrow T-L7)dC, S(S-L8 \rightarrow T-L8)dC, S(S-L7/L8 15 \rightarrow T-L7/L8)dC, T(T-L7 \rightarrow S-L7)dC, T(T-L8 \rightarrow S-L8)dC, and T(T-L7/L8 \rightarrow S-L7/L8)dC) by 16PCR, restriction enzyme digestion, and ligation. PCR was performed in the following 1718two conditions: 1) PCR was performed to substitute the amino acid residues in the loop with a set of primers (S(S-L7 \rightarrow T-L7)dC, StL7Fw1 and StCDRe; S(S-L8 \rightarrow T-L8)dC, 19StFw and StL8Re1, and StL8Fw1 and StCDRe); and 2) PCR was performed to insert the 2021restriction enzyme site for the digestion and ligation of mannanase gene fragments into pET28a using a set of primers (S(S-L7 \rightarrow T-L7)dC, StFw and StL7Re1; StL7Fw2 and 2223StCDRe; and S(S-L8→T-L8)dC, StFw and StL8Re2; StL8Fw2 and StCDRe) (Table S1). 24The primer sets used to construct the loop-substitution mutants for TfMandC using a 25previously reported procedure are listed in Table S1 [30]. The mutant genes (StW281AdC, StD310AdC, and inactive mutant StE273AdC) were generated by PCR 2627using site-directed mutagenesis (Prime Star GXL DNA polymerase kit; Takara Bio Inc.) with the following of 28primers (StW281A-S: sets

1	5'-CGACCAG <u>GCG</u> GGCGACCGGGACGAGGAC-3'		and	StW281	A-AS:
2	5'-GGTCGCC <u>CGC</u> CTGGTCGGGCGGCCCGCC-3';		and	StD31	0A-S:
3	5'-AACACC <u>GCC</u> CCCGTCCTCGACCTGGCG-3'		and	StD310	A-AS:
4	5'-GACGGG <u>GGC</u> GGTGTTCCCGCTCCACGA-3';		StE273	A-S:	5'-
5	ATCGGGGCGTTCGGCGGGCCGCCCGAC-3'	and	StE2	73A-AS:	5'-

6 GCCGAA<u>CGC</u>CCCGATGACCAGCGGCAG-3') (the underline shows the position
7 changed for alanine) using pET28a-StMandC as a template.

8

9 Mannanase activity assay

Mannanase activity was determined at 40°C for 10 min in a reaction mixture (0.1 mL) containing an appropriate amount of enzyme, 1% (w/v) LBG, 1 mM CaCl₂, and 50 mM piperazine-N,N'-bis-(2-ethanesulfonic acid) PIPES (pH 7.0) [30, 33]. The amount of reducing sugars produced by the reaction was determined using the 3,5-dinitrosalicylic acid method [40]. One unit of mannanase activity was defined as the amount of enzyme that liberates reducing sugars equivalent to 1.0 µmol mannose per min. All activity assays were performed in triplicate.

17

18 Evaluation of GGM5 hydrolysis patterns

19 GGM5 (Megazyme International Ireland Ltd., Bray, Ireland) was derivatized with 20 ethyl 4-aminobenzoate (ABEE) [41]. GGM5-ABEE was hydrolyzed by StMandC and 21 TfMandC, and degradation products were analyzed using an HPLC equipped with a C18 22 column (Cadenza CD-C18, 150 x 4.6 mm, Imtakt Corp., Kyoto, Japan). The samples 23 were eluted using the following gradient with a flow rate of 1.0 mL/min: 20% 24 acetonitrile for 0–2 min, a linear gradient to 50% acetonitrile for 2–15 min, and 50% 25 acetonitrile for 15–20 min. The eluted sugars were detected by UV absorption at 305 nm. 26

27 Evaluation of the kinetic parameters of mannanases

The kinetic parameters of StMandC, TfMandC, StW281AdC, and StD310AdC 1 $\mathbf{2}$ toward mannooligosaccharides (Megazyme International Ireland Ltd., Bray, Ireland) determined using a stopped-assay method involving high-performance 3 were 4 anion-exchange chromatography with pulsed amperometric detection (HPAEC-PAD) (Dionex, Sunnyvale, CA, USA). A Carbopac PA1 column (4×250 mm) (Dionex) with $\mathbf{5}$ 6 an isocratic flow of 100 mM NaOH was used for separation. Assay conditions were 0.02-8 mM M4, 0.04-6 mM M5, 0.04-2 mM M6, and 1-50 mM GGM5 with an 7appropriate amount of enzymes. Aliquots were withdrawn at four time points during the 8 5-60 min incubation time, and the reactions were terminated by boiling. The formed 9 hydrolysis products of GGM5 were determined by HPAEC-PAD. Kinetics for M4-M6 10were determined by following the decrease of substrate after hydrolysis because several 11 products were formed. The k_{cat} and K_m values were determined by relationship between 12substrate concentrations and initial hydrolytic velocities using Origin Software 1314 (Lightstone Corp., Tokyo, Japan).

15

16 Crystallization and data collection of StMandC and StE273AdC with M6

Crystallization was performed using the hanging-drop vapor diffusion method at 1720°C. StMandC and StE273AdC were concentrated to 10 mg/ml in 0.1 M Tris-HCl, pH 187.0. The crystallization condition used was 1.1 M sodium malonate (pH 7.0), 0.1 M 19HEPES (pH 7.0), and 0.5% (v/v) Jeffamine[®] ED-2001 (pH 7.0). Glycerol was used at a 2021concentration of 25% as the cryoprotectant. The structure of StE273AdC in complex with substrate was determined by soaking with M6. X-ray diffraction data of the 2223StMandC crystal was collected on beamline BL44XU at SPring-8 (Hyogo, Japan) at a wavelength of 1.0000 Å using MX255HE CCD detector (Rayonix, USA). The X-ray 2425diffraction data of the StE273AdC crystal was collected on beamline NE3A at the Photon Factory Advanced Ring, KEK (Tsukuba, Japan) at a wavelength of 1.0000 Å using the 2627Q270 CCD detector (ADSC, USA). Both diffraction datasets were collected from single crystals under a stream of nitrogen at 100 K. The diffraction data sets were indexed, 28

integrated, and scaled with XDS [42]. The StMandC crystal belonged to the $P2_12_12_1$ 1 space group with the cell dimensions a = 65.86 Å, b = 100.85 Å, and c = 105.24 Å and $\mathbf{2}$ diffracted to 1.60 Å resolution, and the StE273AdC crystal belonged to the $P2_12_12_1$ 3 space group with the cell dimensions a = 65.71 Å, b = 100.71 Å, and c = 104.74 Å and 4 diffracted to 1.50 Å resolution. The StMandC structure was determined by the molecular $\mathbf{5}$ 6 replacement method with *phenix.automr* [43, 44] using **1BQC** (Protein Data Bank code of Thermobifida fusca KW3 mannanase) as a search model. Two molecules are present in 7the asymmetric unit. The resultant model was automatically rebuilt by ARP/wARP [45] 8 using the calculated phases. The refinement was converged by several cycles of manual 9 model corrections with Coot [46] and refinement using phenix.refine [47]. The 1011 StE273AdC structure was determined by rigid body refinement of the StMandC structure, 12followed by several cycles of manual model corrections with *Coot* [46] and refinement using *phenix.refine* [47]. Ramachandran plot analysis was performed using *MolProbity* 1314 [48]. Coordinates and structure factors have been deposited in the Protein Data Bank under codes **3WSU** and **4Y7E**. Data processing and refinement statistics are given in 15Table 2. The graphical representations were prepared using *PyMOL* (DeLano Scientific; 16The PyMOL Molecular Graphics System, Version 1.5.0.4 Schrödinger, LLC.) and 1718MolSoft [49].

1 Figure legends

Figure 1. GGM5 hydrolysis by StMandC and TfMandC. (A) Schematic representation of GGM5 hydrolysis by mannanases. The parenthesis and numbers show the minus subsites in StMandC and TfMandC. The triangles show the cleavage site for StMandC (closed) and TfMandC (open). (B) HPAEC-PAD analysis of the hydrolysis products. (a) GGM5 and StMandC; (b) GGM5 and TfMandC; and (c) GGM5. (C) HPLC analysis of GGM5-ABEE hydrolysis products. (a) GGM5-ABEE and StMandC; (b) GGM5-ABEE and TfMandC; and (c) GGM5-ABEE.

9

Figure 2. Evaluation of the region involved in GGM5 hydrolysis activity. (A) Schematic 1011 representation of the structures of the parent and chimeric enzymes. Amino acid numbers 12and the length of StMan are shown above and inside the bar, respectively. GGM5 hydrolysis products are shown on the right side of the bar. (B) Alignment of the amino 1314 acid sequences responsible for GGM5 hydrolysis specificity of StMan and TfMan. The numbers represent each amino acid residue. (C) Schematic representation of the 15structures of the loop-substitution mutants. As shown in Fig. 2A, the hydrolysis products 16from GGM5 are shown on the right side of each bar. The "N.D." represents no hydrolysis 1718products detected.

19

Figure 3. HPAEC-PAD analysis of GGM5 hydrolysis products by mutated mannanases. GGM5 was hydrolyzed by chimeric enzymes (A) and loop-substitution mutants of StMandC and TfMandC (B).

23

Figure 4. Overall structure of StMandC and StE273AdC with M6. (A) The superimposed structure of StMandC and StE273AdC with M6. The peptide colors (from purple to red) correspond to the N-terminus to the C-terminus. L1-L8 in the figure shows the loop structures from loop1 to loop8, respectively. Mannose residues are shown as yellow and green sticks. (B) A superimposed structure of StMandC and StE273AdC. Amino acid

residues for mutagenesis in this study are shown. White and blue sticks indicate 1 $\mathbf{2}$ StMandC (free form) and StE273AdC (complex with substrate), respectively. (C) Mannose structure at subsites -2 to +1. Mannobiose at subsites -2 and -1 is shown by a 3 4 green stick. Mannobiose at subsites -1 and +1 which distorted the mannose structure at subsite -1 is shown as a vellow stick. (D) Plus subsite binding residues in StMandC and $\mathbf{5}$ 6 StE273AdC. White and blue sticks indicate StMandC and StE273AdC, respectively. The numbers in the figure indicate subsites. σ_A -weighted F_o - F_c omit map is contoured at 3σ 7(C and D). 8

9

Figure 5. Structural comparison between StE273AdC and *T. fusca* KW3 mannanase (PDB code: **1BQC** and **3MAN**). The minus and plus subsites were compared (A) between StE273AdC and 3MAN, and (B) between StE273AdC and 1BQC, respectively. Green and dark blue sticks indicate StE273AdC and TfMandC. Amino acid residues of StE273AdC, which are related to substrate-binding, are shown in the figure, except for Val263 of 3MAN. Mannose residues from StE273AdC and 3MAN are shown as yellow and gray sticks. The numbers in the panels indicate the subsites.

17

Figure 6. Surface view and superimposed model of StE273AdC with *T. fusca* KW3 mannanase (PDB code: **1BQC**). Surface view of the superimposed model of StMandC (green) and 1BQC (orange) (A), StMandC (B), and 1BQC (C) from the upper (left panel) and side clefts from the reducing terminus (right panel). Mannose residues from StE273AdC are shown as a stick structure. The numbers in the figure indicate the subsites.

24

Figure 7. Hydrolysis products of M5 by StMandC and TfMandC. Hydrolysis products of M5 by StMandC and TfMandC were analyzed by HPAEC–PAD. Hydrolysis products were separated by an isocratic flow of 200 mM NaOH.

28

Figure 8. Primary structure alignment of bacterial mannanases. Alignment focused on 1 $\mathbf{2}$ loop7 and loop8 of bacterial mannanase: (A) similar to StMan and (B) similar to TfMan. The amino acid sequences (A) of StMan from Streptomyces thermolilacinus 3 4 (BAK26781); WP_023591108, Streptomyces violaceusniger mannan endo-1,4-β-mannosidase; YP_004802777, Streptomyces SirexAA-E $\mathbf{5}$ sp. cellulose-binding family protein; CAJ88324, Streptomyces ambofaciens ATCC 23877 6 putative secreted β-mannosidase; WP_018555858, Streptomyces sp. ATexAB-D23 7beta-mannosidase; NP_733506, Streptomyces coelicolor A3(2) β-mannosidase; 8 Streptomyces bottropensis 9 WP 005475300, glycosylhydrolase; YP 003493383, Streptomyces scabiei 87.22 putative secreted glycosyl hydrolase; YP_007859663, 1011 Streptomyces sp. PAMC26508 putative secreted β-mannosidase; YP_004924956, Streptomyces flavogriseus ATCC 33331 glycoside hydrolase 5; WP_004003745, 12Streptomyces viridochromogenes Tue57 putative Secreted 13β-mannosidase; WP 020123328, Streptomyces canus β-mannosidase; WP_020140407, Streptomyces sp. 14 β -mannosidase. The amino acid sequence (B) of TfMan from 15351MFTsu5.1 Thermobifida (AAZ54938); StManII from Streptomyces 16fusca thermoluteus (BAM62868); SlMan from Streptomyces lividans 1326 (AAA26710); ADK91085, 17Streptomyces sp. S27 β -1,4-mannanase; WP_005474921, Streptomyces bottropensis 18CAA20610, Streptomyces coelicolor A3(2) β -mannosidase; 19glycosylhydrolase; CBG75158, Streptomyces scabiei 87.22 putative secreted glycosyl hydrolase; CCA60191, 2021Streptomyces venezuelae ATCC 10712 Endo-1,4-β-xylanase A precursor; CCA60180, ATCC 10712 Endo-1,4-β-xylanase 22Streptomyces venezuelae A precursor: 23YP_008735110, Actinoplanes friuliensis DSM 7358 putative glycosyl hydrolase; YP_007953378, Actinoplanes sp. N902-109 secreted β-mannosidase; WP_020640659, 2425Amycolatopsis balhimycina β-mannosidase; YP_003637895, Cellulomonas flavigena DSM 20109 glycoside hydrolase family protein; YP_004081647, Micromonospora sp. 2627L5 β-mannanase-like protein ; WP_018788190, Micromonospora sp. CNB394 mannan endo-1,4-β-mannosidase; YP_004404351, Verrucosispora maris AB-18-032 glycoside 28

hydrolase family protein. The conserved regions and gaps are indicated by highlight and
(-), respectively. The number of the alignment is indicated by the amino acid residues of
each protein. "*1" shows the species possessed more than two kinds of GH5 mannanase
genes: NP_733506 and WP_005474921 from S. coelicolor A3(2); YP_003493383 and
CBG75158 from S. scabiei 87.22; WP_005475300 and WP_005474921 from S.
bottropensis. "*2" shows the species possessed GH26 mannanase gene in addition to
GH5 mannanase gene.
