**ABSTRACT:** Nonylphenol and short-chain nonylphenol ethoxylates such as NP₂EO are present in aquatic environment as wastewater contaminants, and their toxic effects on aquatic species have been reported. Apoptosis has been shown to be induced by serum deprivation or copper treatment. To understand the toxicity of nonylphenol diethoxylate, we investigated the effects of NP₂EO on apoptosis induced by serum deprivation and copper by using PC12 cell system. Nonylphenol diethoxylate itself showed no toxicity and recovered cell viability from apoptosis. In addition, nonylphenol diethoxylate decreased DNA fragmentation caused by apoptosis in PC12 cells. This phenomenon was confirmed after treating apoptotic PC12 cells with nonylphenol diethoxylate, whereas the cytochrome c release into the cytosol decreased compared to that in apoptotic cells not treated with nonylphenol diethoxylates. Furthermore, Bax contents in apoptotic cells were reduced after exposure to nonylphenol diethoxylate. Thus, nonylphenol diethoxylate has the opposite effect on apoptosis in PC12 cells compared to nonylphenol, which enhances apoptosis induced by serum deprivation. The difference in structure of the two compounds is hypothesized to be responsible for this phenomenon. These results indicated that nonylphenol diethoxylate has capability to affect cell differentiation and development and has potentially harmful effect on organisms because of its unexpected impact on apoptosis.

**Keywords:** Nonylphenol diethoxylate; nonylphenol; apoptosis; cytochrome c; PC12 cells
INTRODUCTION

Alkylphenol ethoxylates (APEOs) are nonionic surfactants found in industrial, institutional, and household products. Nonylphenol ethoxylates (NPEOs) are the most commercially abundant APEOs, representing about 80% of the market (APERC, 2006). NPEOs are often used in non-agricultural pesticides, cosmetic and cleaning products, and correction fluids and inks (Stasinakis et al., 2008). Because of the widespread application of these products, NPEOs enter the environment via industrial effluents and wastewater. NPEOs released into the environment are biodegraded to shorter-chain metabolic intermediates including nonylphenol (NP), nonylphenol monoethoxylate (NP$_1$EO), and nonylphenol diethoxylate (NP$_2$EO) by the loss of ethoxylates (EO) (Ahel et al., 1994), which are more toxic, lipophilic, and stable compared to long chain NPEOs (Ying, 2006; Sharma et al., 2009). In recent years, the toxicity of NPEOs and NP has been studied particularly in the aquatic environment (Vazquez et al., 2005; Soares et al., 2008). The toxicity of NPEOs to aquatic organisms increases as the length of ethoxylates chain decreases (Teneyck and Markee, 2007). NP and short chain NPEOs are frequently identified as major contaminants in waste and even drinking water (Ying, 2006; Soares et al., 2008; Sharma et al., 2009). Recently, these sub-products have been detected in vegetables (Cai et al., 2012).

NP and NPEOs are toxic to both aquatic and terrestrial organisms probably as a result of their interaction with proteins (Scott and Krogh, 2004). NPEOs are produced by a base catalyzed reaction of ethylene oxide with NP (Naylor, 1995). NP and NPEOs have different structures; hence, they disrupt differently the biochemical processes in organisms. It has been reported that enzymes such as P-glycoprotein interact with various NPEO compounds, but not with NP (Loo et al., 1998). NP exhibits stable hydrophobicity and has limited biodegradation potential (Tollefsen et al., 2008). It accumulates in organisms, and causes acute toxicity to algae, clams, shrimp, crustaceans, and fish (Tollefsen et al., 1998). NP and short chain NPEOs have also been reported to interact with intracellular and extracellular estrogen binding proteins (Knudsen and Pottinger, 1999), and to interfere with reproductive functions and normal development of fish (Jobling et al., 1996; Seki et al., 2003).

It was found that more than 80% of the male Medaka exposed to concentrations of 50 μg/L to 100 μg/L NP exhibited gonadal intersex (i.e., intermediate characteristics between males and
females). Treatment with 300 μg/L NP\textsubscript{1}EO produced a similar outcome, indicating that when NP was mixed in NP\textsubscript{1}EO, the toxicity of NP\textsubscript{1}EO was enhanced. Because of the differences in the structure of the two compounds, NP had a much stronger effect on fish and mammals compared to the short chain NPEOs (Balch et al., 2006).

Some studies have demonstrated that NPEOs with relatively small number of EO units (s = 0-30) showed greater cytotoxicity (inhibition of cell proliferation) in human skin fibroblast cells compared to long chain NPEOs (Goto et al., 2004). The genotoxic effects of NPEOs on mammalian cells have also been studied. NPEOs were found to cause direct DNA damage (DSBs, double strand breaks), but did not contribute to reactive oxygen species (ROS) (Toyooka et al., 2012). NPEOs also act as tumor initiators and promoters. In contrast, NP decreases the viability of Raji cells via ROS (Qi et al., 2013). These differences of the effect of NPEOs and NP may be dependent on their structures, although the reason for the observed discrepancy between NP and short chain NPEOs remains unclear.

Most of the research on NPEOs degradation from NP has focused on the growth of reproductive organs in rats (Laws et al., 2000; Lee et al., 1996; Odum et al., 1999). Beside reproductive organs, NP also affects nonreproductive organs, such as kidney and liver (Chapin et al., 1999; Nagao et al., 2001). It has been found that hydroxyl radical formation in the striatum was induced in rats treated with NP, which might contribute to certain stages in the advancement of brain damage (Obata and Kubota, 2000). Furthermore, behavioral alterations were observed in the open-field activity of rat offspring exposed to NP (Ferguson et al., 2000). These findings indicate that NP may affect the central nervous system. Thus, NP deleteriously affects several organs, in addition to adipose tissue and adipocytes (Ferguson et al., 2000; Obata and Kubota, 2000; Masuno et al., 2003). However, the effects of short chain NPEOs on cells or organisms have received comparatively little attention because of its smaller toxicity compared to NP.

Few studies have demonstrated the influence of NPEOs on three cell lines; namely, ASF4-1 cells, Jurkat cells, and NIH3T3 cells, which represent normal human skin fibroblasts, human leukemia cells, and mouse fibroblasts, respectively. Certain NP\textsubscript{70}EO showed no cytotoxicity in any of the cell lines, whereas other NP\textsubscript{10}EO exhibited significant toxicity. NP\textsubscript{10}EO toxicity was caused by detachment of cells due to the structural change of the cell membrane. In addition, it was also shown that cytotoxicity was dependent on the number of EO units in all three cell lines. With
decreasing the number of EO units, cell proliferation was increasingly inhibited (Goto et al., 2004). Moreover, LD50 of NPEOs (s = 1.5, 9, 15, 40, and 50) in *Mysidopsis bahia* was 0.11, 1.41, 2.57, over 100 and over 4110 mg/L, respectively (Goto et al., 2004). These findings indicate that the toxicity of NPEOs increases with decreasing the number of EO units. Further detailed cytotoxicity studies of short chain NPEOs are needed.

PC12 is a rat pheochromocytoma clonal cell line that responds to nerve growth factor by extending neurites, thus acquiring the appearance of neurons (Greene and Tischler, 1976). PC12 cells have become a very suitable model to study neuronal function and differentiation (Vaudry et al., 2002; Ravni et al., 2006). On the other hand, it is well known that apoptosis is induced by serum deprivation in PC12 cells (Maroto and Perez-Polo, 1997). Recently, we have reported that some endocrine disrupters inhibited apoptosis induced by serum deprivation (Yamanoshita et al., 2000; 2001). In addition, we have examined whether NP affects apoptosis in PC12 cells. Our results of DNA fragmentation and relative expression of apoptotic factors indicated that NP enhances apoptosis induced by serum deprivation in PC12 cells (Aoki et al., 2004). The effects of short chain NPEOs on apoptosis have not been clarified, although it is expected that the toxicity of NPEOs will decrease with increasing the number of EO units. Apoptosis is a physiological cell-death mechanism commonly associated with programmed events, including morphological and biochemical changes, which are necessary for the differentiation and development of organs and organisms (Maroto and Perez-Polo, 1997). Investigation of effects on apoptosis is expected to contribute new insight into the mechanisms of the effect of NPEOs on the differentiation and development of an organism. In addition, PC12 cells are a good model for study of apoptotic changes because apoptotic condition can be regulated by bovine fetal albumin (Maroto and Perez-Polo, 1997) and copper (Kawakami et al., 2008). The objective of our study is to investigate the role of NPEOs regulation of the changes of apoptotic status caused by serum deprivation or copper, and to clarify the mechanisms of the effects of short chain NPEOs on apoptotic conditions. The significance of obtained results was discussed in detail.

**MATERIALS AND METHODS**

**Materials**
PC12 cells were purchased from the American Type Culture Collection (USA and Canada). Dulbecco’s modified Eagle medium (DMEM), ribonuclease A and o-phenylenediamine dihydro chloride (OPD) were obtained from Sigma-Aldrich (St. Louis, MO, USA). NP₂EO was purchased from Tokyo Chemical Industry Corporation (Tokyo, Japan). Fetal bovine serum (FBS) was obtained from HyClone (Rockville, MD USA). Monoclonal antibody against cytochrome c, and polyclonal antibody against Bcl-2 were from Santa Cruz Biotechnology (Santa Cruz, CA, USA). Nonradioactive cytotoxicity assay kit and purified horseradish peroxidase conjugate of goat anti-mouse IgG (H+L) were obtained from Promega (Madison, WI, USA). Polyclonal antibody against Bax was provided by Calbiochem (San Diego, CA, USA). Anti-rabbit immunoglobulin peroxidase conjugate was obtained from Amersham Bioscience UK Limited (UK). Amersham™ ECL™ western blotting detection reagents were obtained from GE Healthcare UK Limited (UK). The High Pure PCR template Preparation Kit for genomic DNA and Proteinase K was obtained from Roche Diagnostics (Basel, Switzerland). Trypan blue stain solution (0.5%) was obtained from Bio-Rad (Hercules, CA, USA). The Cytochrome c Releasing Apoptosis Assay kit was from Medical and Biological Laboratories Co., Ltd (Japan). All other chemicals were analytical grade.

**Cell Culture**

PC12 cells were cultured in DMEM supplemented with 10% FBS in a humidified incubator at 37°C and 5% CO₂. The cells were pre-incubated overnight in Nunclon™ Delta treated 25-cm² flasks (ThermoFisher Scientific; Waltham, MA, USA), and the medium was then replaced with serum/serum-free DMEM with and without NP₂EO, and serum DMEM containing CuSO₄ with and without NP₂EO. Before the transfer to the serum-free medium that was replaced with medium without serum, the cells in the flask were washed twice with serum-free DMEM.

**Cell Viability**

Cell viability was measured by trypan blue exclusion assay. PC12 cells were incubated in the serum and serum-free medium with 0–1 µg/mL of NP₂EO or serum medium containing 0–500 µM copper with and without NP₂EO for 72 h. After incubation, the cells were stained in 0.25% trypan blue solution in phosphate-buffered saline (PBS). Total cells and trypan blue-stained cells were counted.
using a hemocytometer (TC10™ Automated Cell Counter, Bio-Rad). Cell viability was expressed as a percentage against the total cell number in each experiment. Each experiment was repeated 3–6 times.

DNA Extraction from PC12 Cells

The PC12 cells were incubated in serum/serum-free DMEM containing 0–1 μg/mL NP2EO or serum DMEM containing 0–500 μM CuSO4 with and without NP2EO for 72 h. After the treatment, the cells were harvested with a scraper and transferred into 15-mL tubes. The cells were washed with 1× PBS. Genomic DNA was isolated with High Pure PCR Template Preparation Kit following the manufacturer’s instructions. Finally, the DNA was recovered using ethanol precipitation method.

The DNA ladder pattern was quantified using agarose gel electrophoresis. From 3 μg to 5 μg of DNA was subjected to electrophoresis on 1.5% agarose gel. After electrophoresis, the gel was soaked in ethidium bromide solution for 15 min in the dark, and DNA was visualized and photographed under UV illumination with ChemiDoc XRS (Bio-Rad) to determine the extent of cell death. Density of the DNA ladder was estimated by Image J software.

Western Blotting Analysis of Cytochrome c Release in Cytosol

Cytochrome c release in the cytosol was assessed using Cytochrome c Release Apoptosis Assay Kit (Calbiochem, Darmstadt, Germany). The cells prepared following kit instructions were disrupted by sonication for 30 s in a Sonifier 250 (Branson Ultrasonic). Lysed cells were separated from the intact cells by centrifugation at 650×g for 5 min. Each supernatant was transferred into a separate 1.5-mL tube and centrifuged at 10,000×g at 4°C for 30 min. The treated lysate including released cytochrome c (20–30 μg proteins) was separated by polyacrylamide gel electrophoresis (12.5% polyacrylamide for the separation gel and 3% for the stacking gel), and the electrophoresed proteins were transferred to nitrocellulose membranes with a wetting blotting system, type-AE6678 (ATTO, Tokyo, Japan). The membranes were incubated overnight at 4°C in 0.15% Tween-20, 40 mM Tris–HCl buffer, pH 7.4, containing 150 mM NaCl and 2.5 g dry non-fat milk. The membranes were incubated for 45 min at 37°C with anti-cytochrome c antibody (dilution 1: 200) in 0.15% Tween-20, 40 mM Tris–HCl buffer (pH 7.4), and 150 mM NaCl. The membranes were washed with the same buffer for
3 min 3 times, and then incubated at 37°C for 30 min using anti-mouse IgG-conjugated peroxidase as a secondary antibody (dilution; 1: 2500) in the same buffer. The membranes were washed for 3 min 5 times. Finally, the protein bands that responded to antibodies were detected with an enhanced chemiluminescence imaging system (ChemiDoc XRS, Bio-Rad). The cytochrome c content was measured using Image J software.

**Enzyme Linked Immune-Sorbent Assay (ELISA) of BAX and BCL-2 in PC12 Cells**

The ELISA procedure was carried out according to Yamanoshita et al. (2000). The cells under different experimental settings were washed with 1×PBS and harvested by centrifugation at 650×g for 5 min. The cells were resuspended in the lysis buffer consisting of 2 mM HEPES, 100 mM NaCl, 10 mM EGTA, 1 mM PMSF, 1 mM Na3VO4, 0.1 mM Na2MoO4, 5 mM b-glycerophosphoric acid disodium salt, 50 mM NaF, 1 mM MgCl2, 2 mM DTT, and 1% TritonX-100, and disrupted by sonication (Branson Sonifier 250) for 30 s. The cell debris and intact cells were removed by centrifugation. The contents of BAX and BCL-2 in the cell extracts of the sample solution were measured by ELISA. In brief, 100 μL of each sample was placed in titerplate wells. The plate was incubated for 1 h at 37°C. After the incubation, the titerplate was washed twice with 40 mM Tris–HCl buffer, pH 7.4, containing 150 mM NaCl and 0.05% Tween-20 and blocked by adding 200 μL of the same buffer containing 2% blocking reagent. The plates were then incubated for 1 h at 37°C. The first antibody for BAX or BCL-2 (1:750 or 1:100 diluted with the same buffer) was immobilized with antigens in the samples for 1 h at 37°C. Then, the plate was washed with the same buffer 3 times. The second antibody, an anti-rabbit immunoglobulin peroxidase (1:500 diluted with the same buffer), was added and the plate was incubated for 1 h at 37°C. Then the plate was washed with the same buffer 5 times. After washing, 0.1% OPD in 50 mM phosphate-citrate buffer, pH 5.0, containing 0.03% sodium perborate was added into the wells. After 10 min, HCl was added to stop the enzyme reaction. Absorbance at 495 nm was measured with Microplate Reader model 450 (Bio-Rad).

**Statistical Analysis**

Each value is expressed as the mean ± S.E. Statistical analyses were performed by the student’s
RESULTS

Cell Viability
To evaluate the cytotoxicity of NP₂EO, cell viability was measured by trypan blue staining after the PC12 cells were exposed to 0, 0.1 and 1 μg/mL NP₂EO for 72 h. As shown in Fig. 1A, no significant difference in viability was observed in cells exposed to 0.1 or 1 μg/mL NP₂EO compared to the viability of cells cultured in serum medium without NP₂EO. A significant decrease in viability was observed in cells cultured in the serum-free medium free of NP₂EO. Furthermore, after the addition of NP₂EO to the serum-free medium, a significant increase of cell viability was observed between 0.1 and 1 μg/mL NP₂EO (Fig. 1B).

Cell viability in the serum medium containing CuSO₄ (500 μM) decreased significantly (Fig. 2). When copper and NP₂EO were co-present in the medium for PC12 cells, cell viability significantly increased compared to the cells exposed to copper only. Therefore, NP₂EO recovers viability of copper treated cells.

DNA Fragmentation by Agarose Gel Electrophoresis
To investigate the effect of NP₂EO on apoptosis, DNA fragmentation of PC12 cells cultured in serum/serum-free medium with and without NP₂EO was studied (Fig. 3).

DNA fragmentation was observed when apoptosis was induced by serum-deprivation in the cells (Fig. 3B), and it was absent in PC12 cells cultured in the serum containing medium with 0-1 μg/mL NP₂EO (Fig. 3A). These results indicate that NP₂EO does not induce apoptosis in PC12 cells. On the other hand, the DNA ladder pattern gradually decreased in cells cultured in the serum-free medium in a dose-dependent manner of NP₂EO (Fig. 3B). In addition, the densities of the DNA ladders also decreased when the cells were exposed to 0.1 or 1 μg/mL NP₂EO (Fig. 3C). These results indicate that NP₂EO reduce the apoptosis induced by serum deprivation in PC12 cells.

As expected, the same DNA fragmentation pattern was observed in the serum medium containing CuSO₄ (500 μM) treated with 0.1 or 1 μg/mL NP₂EO (Fig. 4A). NP₂EO reduced the DNA fragmentation in the cells grown in serum medium containing CuSO₄, with the densities of DNA
ladders also decreasing when the cells were exposed to 0.1 or 1 μg/mL NP2EO (Fig. 4B).

**Detection of Cytochrome c Release by Western Blotting**

As shown in Fig. 5B, no significant changes in cytochrome c release were observed among the cells cultured in serum medium with and without N2PEO. These results further confirmed that NP2EO does not induce apoptosis. Yet, after treating PC12 cells with NP2EO in the serum-free medium, cytochrome c content declined in comparison to the PC12 cells without NP2EO (Fig. 5A). Hence, relatively low concentrations of NP2EO might inhibit the apoptosis induced by serum deprivation in PC12 cells.

Furthermore, the cytochrome c release decreased significantly in PC12 cells cultured in serum medium containing copper with 0.1 or 1 μg/mL NP2EO (Fig. 6). Thus, NP2EO reduced the cytochrome c release under the apoptotic situation caused by copper.

**Contents of BAX, BCL-2 in PC12 Cells by ELISA**

To examine whether bcl-2 family is related to reduction of apoptotic situation caused by NP2EO, the contents of BAX and BCL-2 were measured by ELISA after PC12 cells were exposed to 0-1 μg/mL NP2EO for 24 h (Fig. 7). NP2EO significantly decreased BAX contents in PC12 cells cultured in serum-free medium (Fig. 7A). However, as shown in Fig. 7B, there was no significant difference in the contents of BCL-2 between the cells cultured in serum-free medium with and those without NP2EO.

Similarly, the content of BAX decreased significantly in PC12 cells cultured in serum medium containing copper with 0.1 or 1 μg/mL NP2EO (Fig. 8A), although the content of Bcl-2 did not change significantly in the cells cultured on copper containing medium with and without NP2EO (Fig. 8B).

**DISCUSSION**

This study confirmed that NP2EO inhibits apoptosis induced by serum deprivation through examining cell viability (Fig. 1), DNA fragmentation (Fig. 3), and by copper exposure through cell
viability (Fig. 2), DNA fragmentation (Fig. 4). In addition, there was no cytotoxicity in PC12 cells cultured in serum containing medium with 0.1 or 1 μg/mL NP$_2$EO, and DNA fragmentation was not observed in these cells (Fig. 3A). The results indicated that the short chain NPEOs do not induce apoptosis. However, compared to PC12 cells without NP$_2$EO, the cytotoxicity of cells increased when exposed to 0.1 or 1 μg/mL NP$_2$EO under apoptotic conditions caused by serum deprivation (Fig. 1B), whereas NP$_2$EO caused a significant decrease in DNA fragmentation (Fig. 3C). These results indicated that NP$_2$EO inhibits apoptosis caused by serum deprivation. This finding is additionally supported by the results presented in Fig. 2. These results suggest that NP$_2$EO could significantly recover the cytotoxicity of cells exposed to CuSO$_4$ because CuSO$_4$ is known to induce apoptosis (Woodgate et al., 1999). In addition, DNA fragmentation decreased with addition of NP$_2$EO (Fig. 4). These results indicated that NP$_2$EO inhibits apoptosis activity caused by copper exposure.

It has been demonstrated that NP induces apoptosis (Bechi et al., 2006; Kuo et al., 2012). Furthermore, Aoki et al. (2004) reported that NP enhances apoptosis induced by serum deprivation. Yet, the current study showed that NP$_2$EO did not induce apoptosis, and that it inhibited apoptosis induced by serum deprivation and copper exposure. Previous studies have indicated that NP cytotoxicity was higher than the short chain NPEOs (Teneyck and Markee, 2007). Therefore, the strength of toxicity might depend on the length of EO chain, because NP can be defined as NP$_0$EO.

The current study also aims to determine whether oxidative stress contributes to the observed changes in apoptotic status caused by short chain NPEOs. Cytochrome c release in apoptotic PC12 cells that were and were not exposed to NPEOs was measured by western blotting. Serum deprivation and copper exposure increased the amount of cytochrome c release from mitochondria (Figs. 5 and 6). This increase was because of the disruption of mitochondrial membrane caused by ROS production (Atlante et al., 2000; Kawakami et al., 2008). The cytochrome c release decreased when PC12 cells were exposed to NP$_2$EO under the apoptotic condition. These results might be due to NP$_2$EO causing a reduction in oxidative stress. However, previous research showed that NP exposure induced apoptosis in the liver of malt rats, and enhanced the expression of cytochrome c with increasing oxidative stress (Jubendradass et al., 2012). EO chain length might influence the difference in the toxicity between NP and short chain NPEOs; however, the actual mechanism remains unclear. To elucidate the different toxicity of these two compounds, examination of NP$_2$EO under the apoptotic conditions is required.
Serum deprivation has been reported to induce apoptosis in PC12 cells (Maroto and Perez-Polo, 1997). Results obtained in our laboratory suggested that NP enhanced apoptosis by serum deprivation in PC12 cells (Aoki et al., 2004) as indicated by the caspase-3 pathway. In comparison, the contents of BAX and BCL-2 from the BCL-2 family were not altered, with only the content of BAD increasing. These results indicated that enhanced apoptotic cell death might be dependent on the pathway regulating the release of cytochrome c from mitochondria. It has been reported that cytochrome c is released from the mitochondria when apoptosis is induced (Gao et al., 2001). In the current study, it was observed that the relative release of cytochrome c in PC12 cells treated with NP2EO decreased in serum-free medium and medium containing copper. In addition, the contents of BAX from the BCL-2 family decreased significantly in PC12 cells under apoptotic conditions after exposure to NP2EO (Figs. 7 and 8). These results indicated that NP2EO might inhibit apoptotic pathway because of reduction of Bax contents. It has been reported that tributyl tin and 2,4,5-T completely inhibit apoptosis induced by serum deprivation, decreasing both Bax and pro-apoptotic protein content (Yamanoshita et al., 2000; 2001). Hence, NP2EO might have a similar impact on the apoptosis of PC12 cells to these compounds. Therefore, the addition of NP2EO affects Bcl-2 family protein expression, and hence, affects apoptosis induced by serum deprivation or copper exposure.

In conclusion, NP2EO inhibited apoptosis induced by serum deprivation and copper. NP2EO exhibited the opposite effect on apoptosis in PC12 cells compared to NP, which might be due to the difference in the structure of the two compounds, along with different response mechanisms to apoptosis. Ultimately, further investigation is required to clarify the precise toxicity mechanism of short chain NPEOs and NP.

Fig. 4 DNA fragmentation of PC12 cells cultured in serum containing medium with 0–500 μM CuSO₄ and 0–1 μg/mL NP₂EO for 72 h (A). Fragmentation was evaluated by the measurement of DNA ladder patterns (B) and the density (C). M indicates λDNA digested by HindIII as a DNA marker. Error bars indicate SEM (n = 3). * and ** indicate significant differences at p < 0.05 and p < 0.01, respectively.

Fig. 5 Representative western blot analyses for cytochrome c release in PC12 cells cultured in serum-containing medium (A) and serum-free medium (B) for 72 h after exposure to 0–1 μg/mL NP₂EO. Error bars indicate SEM (n = 3). The typical pattern and mean intensity of staining by representative western blot analyses are shown in the upper and lower panels of the figure, respectively. * and ** indicate significant differences at p < 0.05 and p < 0.01, respectively.

Fig. 6 Representative western blot analyses for cytochrome c release in PC12 cells cultured in serum medium containing 0–500 μM CuSO₄ for 72 h after exposure to 0–1 μg/mL NP₂EO. Error bars indicate SEM (n = 5). The typical pattern and mean intensity of staining by representative western
blot analyses are shown in the upper and lower panels of the figure, respectively. * and ** indicate significant differences at $p < 0.05$ and $p < 0.01$, respectively.

Fig. 7 The contents of BAX (A) and BCL-2 (B) in PC12 cells cultured in serum-containing medium or serum-free medium for 24 h after exposure to $0–1 \, \mu g/mL \, NP_2EO$. Error bars mean SEM $(n = 6)$. * and *** indicate significant differences at $p < 0.05$ and $p < 0.001$, respectively.

Fig. 8 The contents of BAX (A) and BCL-2 (B) in PC12 cells cultured in serum medium containing $0–500 \, \mu M \, CuSO_4$ for 72 h after exposure to $0–1 \, \mu g/mL \, NP2EO$. Error bars mean SEM $(n = 6)$. * and *** indicate significant differences at $p < 0.05$ and $p < 0.001$, respectively.
