Abstract. A novel approach has been developed for the synthesis of chiral 3-boryl-tetrahydroquinolines via the copper(I)-catalyzed regio- and enantioselective protoborylation of 1,2-dihydroquinolines, which were prepared by the partial reduction of the corresponding quinoline derivatives. This dearomatization/enantioselective borylation sequence has been used to provide facile access to a wide variety of functionalized tetrahydroquinolines under mild conditions from readily available quinoline starting materials in combination with the stereospecific transformation of a stereogenic C–B bond. A theoretical study of the mechanism for the enantioselectivity of the reaction has also been described.

Keywords: Asymmetric catalysis; Boron; Copper; Synthetic methods

Many pharmaceutical agents and bioactive natural products contain an optically active substituted tetrahydroquinoline scaffold.[1] In particular, chiral 3-substituted tetrahydroquinolines can be found in a wide range of drugs exhibiting a broad spectrum of biological activities (Scheme 1). [2] Based on their interesting properties, there has been considerable interest in the development of novel synthetic methods for the preparation of substituted tetrahydroquinolines from researchers working in organic and medicinal chemistry.[3]

Optically active organoboron compounds are recognized as useful chiral building blocks in synthetic chemistry because they can be readily applied to the stereospecific functionalization of stereogenic C–B bonds.[4] Considering their great synthetic utility, chiral N-heterocyclic organoboronates represent promising intermediates for the preparation of various bioactive molecules and pharmaceutical drugs.[5-7] Despite significant progress toward the development of synthetic approaches for the preparation of chiral boronates, reports pertaining to the catalytic enantioselective construction of these compounds remain scarce.[1,5-7]

Figure 1. Representative bioactive tetrahydroquinolines.

We recently reported a novel approach to chiral 3-boryl-tetrahydropyridines via the copper(I)-catalyzed regio-, diastereo- and enantioselective borylation of 1,2-dihydropyridines, which were prepared by the partial reduction of the corresponding pyridine derivatives (Scheme 1a).[7,8] This dearomatization/enantioselective borylation sequence provided direct access to chiral piperidines from readily available pyridines in combination with the stereospecific transformation of a stereogenic C–B bond.[9] More recently, we turned our attention to the synthesis of chiral boryl-tetrahydroquinolines from quinolines using this sequential dearomative reduction/borylation strategy (Scheme 1b). Pleasingly, we found that the enantioselective protoborylation of 1,2-dihydroquinolines, which were readily prepared by the partial reduction of the corresponding quinolines, in the presence of a copper(I)/(R,R)-QuinoxP* complex catalyst proceeded smoothly to afford the chiral boronates in high yields with excellent regio- and enantioselectivities.[10-13] Furthermore, the chiral...
boronate products could be further functionalized in a stereospecific manner via the oxidation or amination of their C–B bond.

The results of an extensive series of optimization experiments revealed that the reaction of N-acetyl 1,2-dihydroquinoline 2a, which was prepared by the reduction of quinolone (1a) with NaBH₄, with bis(pinacolato)diboron (3) (1.2 equiv.) in the presence of CuCl/(R,R)-QuinoxP* (5 mol %), K(O-t-Bu) (20 mol %) and MeOH (2.0 equiv.) in THF at −10 °C afforded the desired chiral 3-boryl-tetrahydroquinoline (R)-4a in high yield (90%) with excellent enantioselectivity (99% ee) (Table 1, entry 1). The use of (R,R)-BenzP* or (R,R)-Me-Duphos also provided high levels of enantioselectivity (Table 1, entries 2 and 3, 97 and 95% ee, respectively). Lower chemical yields and enantioselectivities were observed when a triarylphosphine-type ligand, such as (R)-Josiphos, was also screened in the reaction. Although these ligands both provided access to the desired borylation product, they afforded poor enantioselectivities (Table 1, entries 6 and 7; −14 and −29% ee, respectively). The nature of the proton source was also found to be important to the success of this transformation (Table 1, entries 8 and 9). For example, the use of sterically hindered t-BuOH instead of MeOH resulted in a lower yield of the desired product (Table 1, entry 8; 39%, 95% ee). Furthermore, the use of PhOH as a proton source provided a low yield, despite affording a high enantioselectivity (Table 1, entry 9; 48%, 98% ee).

These results therefore suggest that the proton source is not involved in the enantiodetermining step of this reaction. Notably, this enantioselective borylation reaction also proceeded with a 1 mol % loading of the copper(I) catalyst and showed good enantioselectivity (87% ee), although a longer reaction time was required (Table 1, entry 10). Increasing the temperature of the reaction led to a slight decrease in the enantioselectivity (Table 1, entry 11; 85%, 95% ee). The reaction proceeded smoothly on a gram scale to give the desired product (1.53 g) with excellent enantioselectivity (Table 1, entry 12, 97% ee).

[a] Conditions: CuCl (0.025 mmol), ligand (0.025 mmol), 2a (0.5 mmol), bis(pinacolato)diboron (3) (0.6 mmol), K(O-t-Bu) (0.1 mmol) and alcohol (1.0 mmol) in THF (1.0 mL).

[b] Determined by 1H NMR analysis of the crude reaction mixture with an internal standard.

c) Determined by HPLC analysis.

d) 1 mol % CuCl and ligand were used in this reaction with a reaction time of 24 h.

e) The reaction was carried out at 30 °C.

With the optimized conditions in hand, we provided to evaluate the substrate scope of the reaction using a series of substituted quinolones (Table 2). The borylation products in Table 2 were isolated as the corresponding silyl ethers following the sequential oxidation/silylation of their C–B bonds (Please see Scheme 2 and the Supporting Information for further details). 1,2-Dihydroquinolines bearing a Me-, t-Bu-, MeO- or TIPS group at their 6-position (2b–e) reacted smoothly in the presence of the copper(I)/(R,R)-QuinoxP* catalyst system to give the desired products [(R)-4b–(R)-4d] with high
enantioselectivities (93–98% ee) (Table 2). In contrast, substrates bearing an electron-withdrawing group such as a halogen or nitro group (2f–2h) provided only moderate enantioselectivities (68–73% ee) (Table 2). Fortunately, the borylations of 2f and 2g with (R,R)-BenzP* instead of (R,R)-QuinoxP* showed high enantioselectivities (97% ee and 96% ee, respectively). The 7-methyl substituted 1,2-dihydroquinoline 2i was also borylated under the optimized conditions to afford the corresponding 3-boryl-tetrahydroquinoline [(R)-4i] with excellent enantioselectivity (93% ee) (Table 2). The borylation of the 7-bromo substituted 1,2-dihydroquinoline 2j also proceeded well with high enantioselectivity (87% ee) (Table 2). The copper(I)/(R,R)-QuinoxP* complex also performed as an effective catalyst for the enantioselective protoborylation of the carbamate-protected substrate 2k, which was prepared by a NaBH₄ reduction,[16] to give the corresponding borylation product [(R)-4k] in high yield (84%) and enantioselectivity (98% ee) (Table 2).

[a] Conditions: CuCl (0.025 mmol), (R,R)-QuinoxP* (0.025 mmol), 2 (0.5 mmol), bis(pinacolato)diboron (0.6 mmol), K(O-t-Bu) (0.1 mmol) and MeOH (1.0 mmol) in THF (1.0 mL).
[b] 1H NMR yields of the borylation products. The isolated yields of the corresponding silyl ethers 5 after the sequential oxidation/silylation of the borylation products 4 are shown in parenthesis.
[c] (R,R)-BenzP* was used instead of (R,R)-QuinoxP*.

The borylation products generated in this study could be used as versatile building blocks for the preparation of a wide range of chiral tetrahydroquinolines. For example, the oxidation of the crude mixture resulting from the borylation of 2a with NaBO₃,[17] followed by the sequential silylation of the resulting alcohol afforded the chiral tetrahydroquinolinol (R)-5 with high enantiomeric excess (Scheme 2). Furthermore, the amination[18] of the crude product (R)-4a with BnN₃ provided the chiral amine (R)-6 in a stereospecific manner (Scheme 2). Lastly, the oxidation of compound (S)-4k, which was prepared by the borylation of 2k with (S,S)-QuinoxP*, afforded the known chiral alcohol (S)-7 in 3 steps from quinoline. Notably, compound (S)-7 is an important intermediate in the synthesis of Sumanirole.[2b]

Scheme 2. Synthesis of functionalized chiral tetrahydroquinolines through the derivatizations of the borylation products.

DFT calculations (B3PW91/cc-pVDZ) were conducted to elucidate the mechanism responsible for the enantioselectivity of the current reaction for the borylation of 1,2-dihydroquinolines (Figure 2). The results revealed that the addition of the (R,R)-QuinoxP*/borylcopper(I) complex to the Si-face of the 1,2-dihydroquinoline 2a would give transition state TS1,[19] which would be free from steric congestion between the t-Bu group of the ligand and the 1,2-dihydroquinoline scaffold. This reaction pathway would therefore afford the (R)-isomer as the major product, which is consistent with the observed absolute configuration of the borylated product.[20] In contrast, the activation barrier for the addition of the complex to the Re-face to give transition state TS2 was +3.35 kcal/mol higher in energy than that of TS1. This difference in the activation barrier was attributed to steric congestion between the t-Bu group of the ligand and the 1,2-dihydroquinoline scaffold. This reaction pathway would therefore afford the (R)-isomer as the major product, which is consistent with the observed absolute configuration of the borylated product.[20] In contrast, the activation barrier for the addition of the complex to the Re-face to give transition state TS2 was +3.35 kcal/mol higher in energy than that of TS1. This difference in the activation barrier was attributed to steric congestion between the 1,2-dihydroquinoline 2a and the t-Bu group on the ligand in TS2, thereby explaining the observed enantioselectivity of this reaction.
at the Global Facility Center, Hokkaido University.

High-resolution mass spectra were recorded on a Hitachi LaChrom Elite HPLC system equipped with a L-2400 UV detector. GLC analyses were conducted on a Shimadzu GC-2014 or GC-2025 system (Shimadzu, Kyoto, Japan) equipped with an FID detector. HPLC analyses were conducted over a chiral stationary phase on a Hitachi Chemical Industries) and an FID detector. The sealed vial was then connected to a vacuum/nitrogen manifold through a needle and vacuum purged with nitrogen three times. THF (1.0 mL) was added to the vial through the rubber septum, followed by a 1.0 M solution of K(Ot-Bu) in THF (0.1 mL, 0.1 mmol), and the resting mixture was cooled to −10 °C. A solution of 2a (92.1 mg, 0.53 mmol) in MeOH (40.5 μL, 1.0 mmol) was then added to the cooled mixture at a dropwise manner −10 °C. Upon completion of the reaction, as determined by GC analysis and TLC, the reaction mixture was passed through a short silica gel column eluting with Et₂O. The yield of the borylation product (5)-4a was determined by ¹H NMR analysis with an internal standard (83% NMR yield). The product was isolated following its conversion to the corresponding silyl ether by the oxidation of the boryl group, followed by the TBS protection of the resulting alcohol (78% isolated yield, 3 steps). The details of these transformations have been described in the Supporting Information.

In summary, we have developed a novel approach to chiral 3-boryl-tetrahydroquinolines via the copper(I)-catalyzed regio- and enantioselective protoborylation of 1,2-dihydroquinolines, which were prepared by the partial reduction of the corresponding quinoline derivatives. This new stepwise strategy represents a simple and direct method for the synthesis of optically active tetrahydroquinolines bearing a C3-stereocenter in combination with a stereospecific boron functionalization process.

Experimental Section

General Remarks

Materials were obtained from commercial suppliers and purified by standard procedures unless otherwise noted. Solvents were also purchased from commercial suppliers, degassed via three freeze-pump-thaw cycles and further dried over 4 Å molecular sieves. ¹H and ¹³C NMR spectra were recorded on JEOL JNM-ECX-400P spectrometer at 400 and 100 MHz, respectively. The peaks corresponding to tetramethylsilane (¹H) and CDCl₃ (¹³C) were employed as reference standards in the ¹H and ¹³C NMR spectra, respectively. 1,1,2,2-Tetrachloroethane was used as an internal standard to determine the reaction yields by NMR. GLC analyses were conducted on a Shimadzu GC-2014 or GC-2025 system (Shimadzu, Kyoto, Japan) equipped with a ULBON HR-1 glass capillary column (Shinwa Chemical Industries) and an FID detector. HPLC analyses were conducted over a chiral stationary phase on a Hitachi LaChrom Elite HPLC system equipped with an L-2400 UV detector. High-resolution mass spectra were recorded at the Global Facility Center, Hokkaido University.

Representative Procedure for Copper(I)-Catalyzed Enantioselective Borylation of 2a.

Copper chloride (2.6 mg, 0.026 mmol), bis(pinacolato)diboron (153.6 mg, 0.6 mmol) and (R,R)-QuinoxP⁺ (8.4 mg, 0.025 mmol) were placed in an oven-dried reaction vial, which was immediately sealed with a screw cap containing a Teflon-coated rubber septum. The sealed vial was then connected to a vacuum/nitrogen manifold through a needle and vacuum purged with nitrogen three times. THF (1.0 mL) was added to the vial through the rubber septum, followed by a 1.0 M solution of K(O-t-Bu) in THF (0.1 mL, 0.1 mmol), and the resting mixture was cooled to −10 °C. A solution of 2a (92.1 mg, 0.53 mmol) in MeOH (40.5 μL, 1.0 mmol) was then added to the cooled mixture at a dropwise manner −10 °C. Upon completion of the reaction, as determined by GC analysis and TLC, the reaction mixture was passed through a short silica gel column eluting with Et₂O. The yield of the borylation product (5)-4a was determined by ¹H NMR analysis with an internal standard (83% NMR yield). The product was isolated following its conversion to the corresponding silyl ether by the oxidation of the boryl group, followed by the TBS protection of the resulting alcohol (78% isolated yield, 3 steps). The details of these transformations have been described in the Supporting Information.

Supporting Information

References

We tried to isolate the borylation product (R)-4a after the reaction, but separation of (R)-4a and pinacol was difficult by silica gel column chromatography. The details have been described in the Supporting Information.

The origin of the regioselectivity of the 4,3-addition of the borylcopper(I) complex to 1,2-dihydropyrrolines can be explained by the formation of more stable benzylic alkylcopper(I) intermediate compared to the corresponding alkylcopper(I) generated at 3-position in the 3,4-addition.

The absolute configuration of the borylation products was determined by comparison of the optical rotation of (S)-7 and the reported values (ref. 2b). The details have been described in the Supporting Information.
