Experimental

1. Synthesis and characterization of NU-1000
The NU-1000 MOF was synthesized by following the reported procedure.\textsuperscript{S1} Powder X-ray diffraction (PXRD) data were collected on a Rigaku model ATX-G diffractometer equipped with a Cu rotating anode X-ray source. N\textsubscript{2} physisorption isotherm measurements were performed on a Micromeritics Tristar II 3020 (Micromeritics, Norcross, GA) at 77 K. Between 30 and 50 mg of material was used for each measurement.

2. Aqueous-phase adsorption of furanics and sugars on NU-1000
To investigate adsorption of furanics and sugars on NU-1000 in aqueous solution, five compounds were employed: 5-hydroxymethylfurfural (HMF); furfural; glucose; fructose; and xylose, which were supplied from Sigma-Aldrich and Acros Organics. An aqueous stock solution containing single component (for single-component adsorption) or multicomponent (for competitive-mode) with high concentration was prepared in a volumetric flask. The stock solution was used as-is or after dilution in Milli-Q water (18 MΩ cm). 5 mg of NU-1000 was dispersed in 1.5 mL of the aqueous solution. We also tested another adsorbent, commercial mesoporous carbon material MSC-30 (Kansai Coke & Chemicals) and carbon black BP2000 (Cabot). The suspension was ultrasonicated for 1 min to disperse the adsorbent well, vortexed for at least 30 min at 297 K, and then filtered with a syringeless filter device Mini-UniPrep equipped with a polytetrafluoroethylene membrane (0.2 μm mesh, Whatman). The amount of residual compound in the liquid-phase filtrate was quantified by high-performance liquid chromatography (HPLC, Shimadzu, Prominence HPLC System, refractive index detector) equipped with an Aminex HPX-87H column (Bio-Rad, ø7.8 × 300 mm, mobile phase 5 mM H\textsubscript{2}SO\textsubscript{4} 0.6 mL min\textsuperscript{-1}, column temperature 323 K), with an absolute calibration method. The subtraction of mass of furanic/sugar detected by HPLC from that of compound charged gave an uptake.

All isotherms observed in this study exhibit Type I behavior (\textit{i.e.}, Langmuir isotherm), except for glucose, fructose, or xylose on NU-1000 (see Figs. 1 and 2) or such sugars on MSC-30 (see Fig. S8). The Langmuir equation [Eq. (S1)] gives the adsorption equilibrium constant ($K_{\text{ads}}$) and adsorption capacity ($Q_{\text{max}}$) for each isotherm.

$$Q = \frac{CK_{\text{ads}}Q_{\text{max}}}{1 + CK_{\text{ads}}} \quad \text{(S1)}$$

where $C$ is the equilibrium concentration and $Q$ is the uptake. This equation is transformed into Eq. (S2), which represents the Langmuir plot.

$$\frac{C}{Q} = \frac{C}{Q_{\text{max}}} + \frac{1}{K_{\text{ads}}Q_{\text{max}}} \quad \text{(S2)}$$

Fig. S8  Competitive adsorption of furanics and sugars on MSC-30, recorded at 297 K: (a) C6 compounds; (b) C5 compounds. The insets represent the expanded figures in the range from 0 M to 0.02 M. The dashed lines represent the isotherms replicated by the Langmuir parameters (Table S5). The Langmuir plots for HMF and furfural are shown in Fig. S9.

At high HMF/furfural concentration, all adsorption sites of MSC-30 are occupied by these furanics, which thus inhibits sugars adsorption. However, in the case of high MSC-30 loading and/or low HMF concentration, sugars adsorb on the surface, in addition to HMF (see Figs. 3 and S10).

^a Ratio of furanic to sugar, based on adsorbed mass. ^b Activated carbon, oxidized by nitric acid. ^c Synthesized via Friedel-Crafts alkylation of 4,4′-bis(chloromethyl)-1,1′-biphenyl. ^d No data. ^e Competitive adsorption data are shown in Fig. 3. ^f The infinite ratio of HMF to fructose can be achieved only when HMF occupies all adsorption sites of BP2000. We should note that BP2000 exhibits fructose uptake in single-component adsorption experiment, and this behavior is contrast to the complete lack of fructose adsorption on NU-1000 even in the absence of HMF (see Fig. 1). ^g Levulinic acid of ca. 100 mg was also adsorbed on 1 g of BP2000. ^h Levulinic acid of ca. 10 mg was also adsorbed on 1 g of ROX-N30.
