Supplement of

Holocene dynamics in the Bering Strait inflow to the Arctic and the Beaufort Gyre circulation based on sedimentary records from the Chukchi Sea

Masanobu Yamamoto et al.

Correspondence to: Masanobu Yamamoto (myama@ees.hokudai.ac.jp)

Supplementary material

Table S1. The quartz/feldspar (Q/F) and Q/F with logarithmic function (log Q/F), (chlorite + kaolinite)/illite (CK/I) and chlorite/illite (C/I) ratios in bulk fraction of the Beaufort Sea surface sediments

Cruise	Station	Latitude (°N)	Longtitude (°E)	Water depth (m)	Q/F	Log Q/F	C+K/I	C/I

udl: under detection limit.

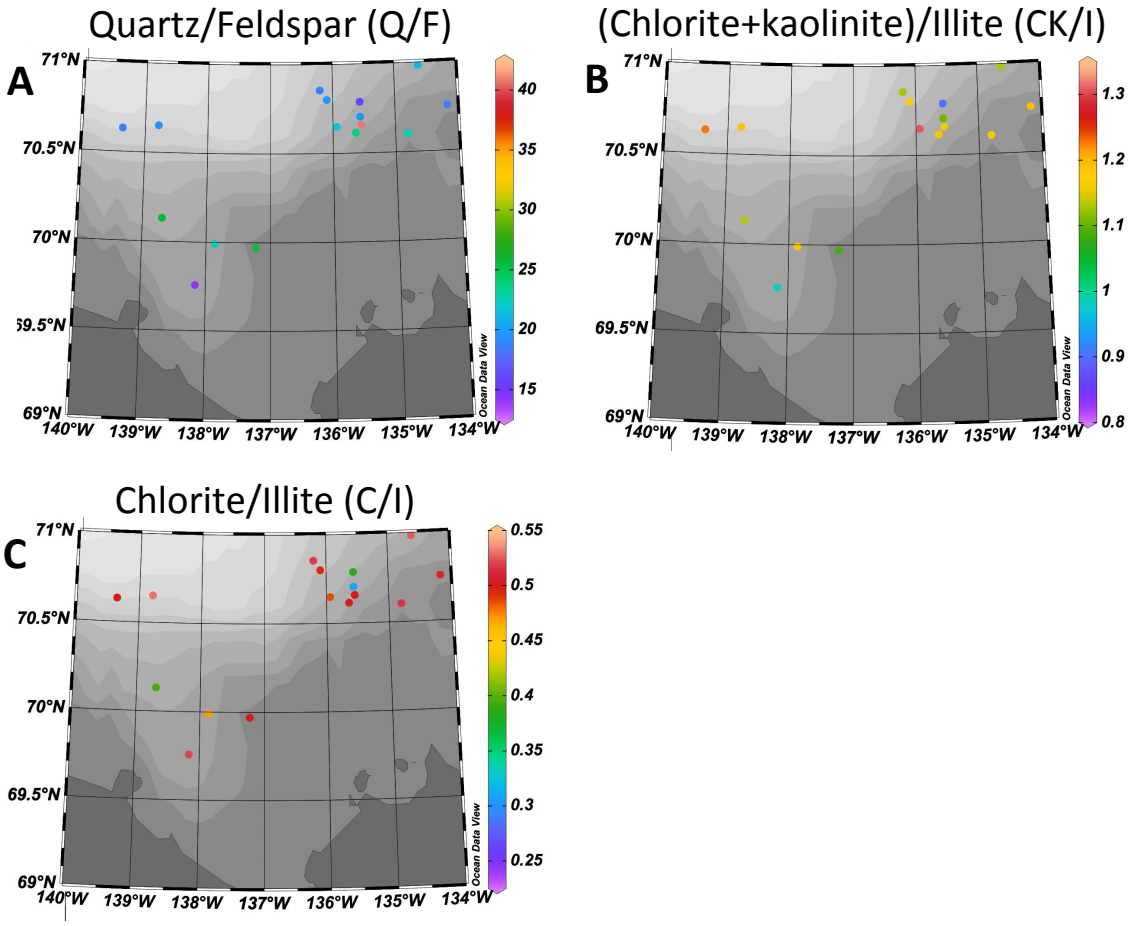

Fig. S1. Spatial distributions of the diffraction intensity ratios of (A) feldspar to quartz (Q/F), and of (B) chlorite+kaolinite and (C) chlorite to illite (CK/I and C/I, respectively) of bulk sediments in the Mackenzie River estuary.

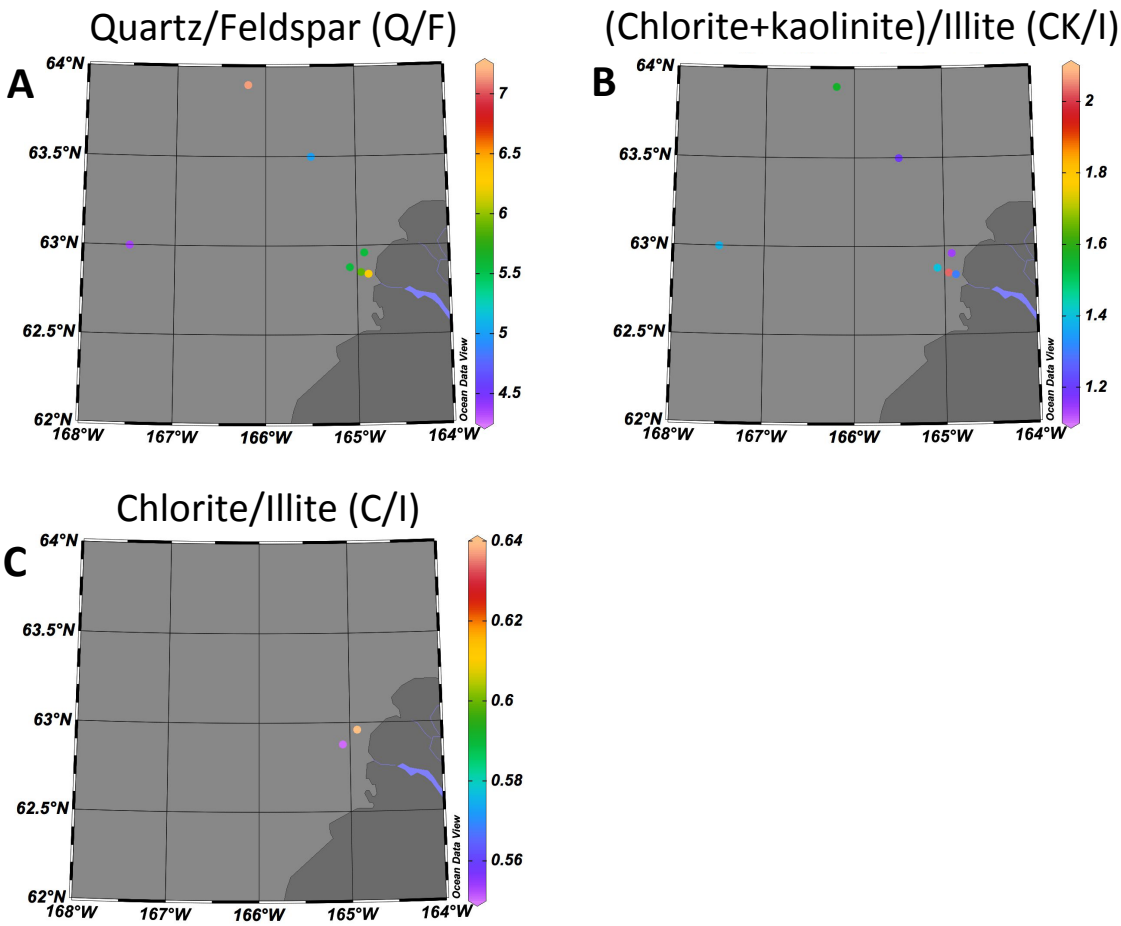

Fig. S2. Spatial distributions of the diffraction intensity ratios of (A) feldspar to quartz (Q/F), and of (B) chlorite+kaolinite and (C) chlorite to illite (CK/I and C/I, respectively) of bulk sediments in the Yukon River estuary.

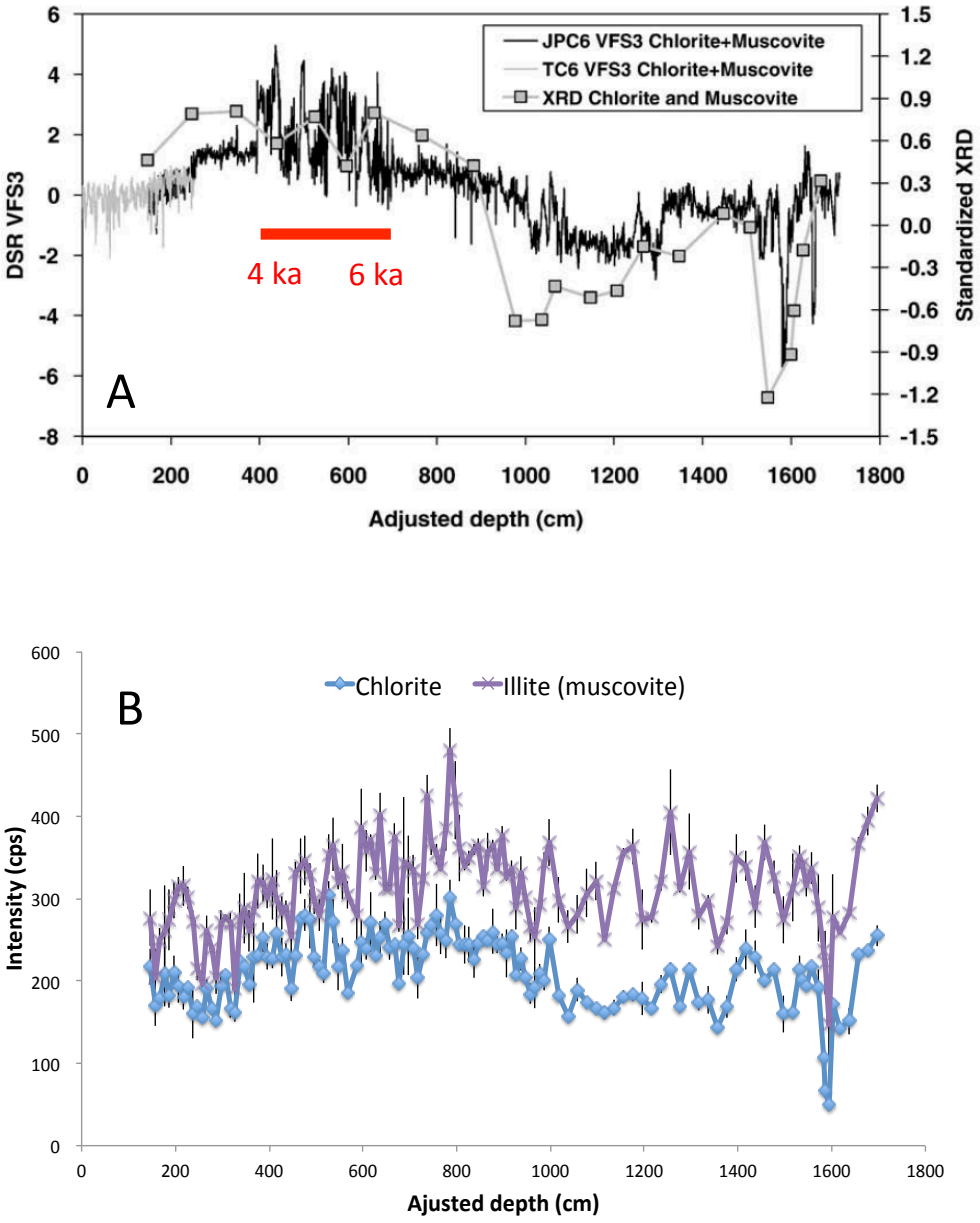

Fig. S3. (A) Chlorite proxy obtained by diffusive spectral reflectance analysis (DSR VFS3) and the abundance of chlorite+muscovite obtained by quantitative XRD analysis (Ortiz et al., 2009) and (B) XRD peak intensities of chlorite at 25.1°2θ (d = 3.54 Å) and illite (muscovite) at 8.8°2θ (d = 10.1 Å) in core HLY0501-06JPC obtained in this study. The changing pattern of peak intensities of chlorite and illite (Panel B) generally agrees well with that of chlorite proxy (Panel A), but the peak intensities do not culminate between 400 and 700 cm in contrast to chlorite proxy.
