Abstract

Incretin-related drugs, such as dipeptidyl peptidase-4 (DPP-4) inhibitors and glucagon-like peptide-1 (GLP-1) analogues, have been clinically available and widely used to treat patients with type 2 diabetes mellitus. Accumulating evidence indicates that these agents exert glycemic control and have various other favorable effects, including prevention of atherosclerosis. It is important to assess and manage early-phase atherosclerosis, but whether diabetic therapeutics including incretin-related drugs improve or maintain vascular endothelial cell function has not been fully determined. We previously published prospective clinical trials focused on flow-mediated dilation in patients with type 2 diabetes, who did not have severe atherosclerosis, using two different incretin-related drugs: a DPP-4 inhibitor and a GLP-1 analogue. These trials showed that these therapeutic agents did not improve endothelial cell function. In this article, we discuss how incretin-related drugs contribute, if at all, to vascular endothelial cell function, atherosclerosis, and beta-cell function, based on our clinical trials and previous evidence.

Key words: GLP-1 analogue; DPP-4 inhibitor; endothelial cell function

INTRODUCTION

Prevention of atherosclerotic diseases, such as cardiovascular disease (CVD) and stroke is an issue that should be resolved in patients with type 2 diabetes mellitus because they have a higher risk of these conditions.¹ Recent comprehensive care of patients with risk factors dramatically decreased diabetic macro- and microvascular complications,² but the mortality rate is still higher in populations with diabetes.³ Therefore, detection and management of the earlier phases of atherosclerosis is important. It has been

reported that endothelial cell damage precedes progressive atherosclerosis and these dysfunctions are known to be individual risk factors for CVD in type 2 diabetes mellitus.^{4,5} For the relationship between therapeutics and endothelial cell function, numerous studies have been performed, and statins⁶ and angiotensin II receptor blockers⁷ along with some anti-diabetic agents were reported to improve endothelial dysfunction.^{8,9}

In recent years, incretin-related drugs such as dipeptidyl peptidase-4 (DPP-4) inhibitors and glucagon-like peptide-1

(GLP-1) analogues, have been available to treat patients with type 2 diabetes mellitus and their anti-atherosclerotic potentials had been expected based on many *in vitro* studies and animal models. However, some longitudinal studies failed to verify their superiority for the prevention of CVD.¹⁰⁻¹² Moreover, their effects on endothelial cell function have been inconsistent.¹³ We performed two different randomized controlled trials that focused on endothelial cell function, using different incretin-related agents, the DPP-4 inhibitor sitagliptin and the GLP-1 receptor agonist liraglutide. Results of these clinical trials demonstrated that both medications did not improve endothelial cell function assessed by flow-mediated dilatation. Here, we will introduce them and discuss the effects of incretin-related therapy on the early phase of atherosclerosis.

THE EFFECT OF INCRETIN-RELATED THERAPY ON ENDOTHELIAL CELL FUNCTION

We investigated whether incretin-related drugs improve endothelial cell function using flow-mediated dilatation (FMD) of the brachial artery. FMD is known to be a less-invasive tool that reflects endothelial nitric oxide bioavailability to evaluate endothelial cell function, and a reversible marker of early phase of atherosclerosis.¹⁴ Additionally, a recent meta-analysis showed that improvement of FMD was significantly related to the relative risk reduction in cardiovascular events.¹⁵ Thus, treatments that have favorable effects on FMD might be ideal for prevention form cardiovascular outcomes. We conducted two open-label, multicenter, prospective randomized parallel-group comparison studies comparing sitagliptin *versus* glimepiride (SAIS-1)¹⁶ and liraglutide *versus* insulin glargine (SAIS-2)¹⁷ (**Table 1**). Briefly, patients with type 2 diabetes mellitus who did not have severe atherosclerotic diseases were randomly assigned to each treatment, and underwent treatment for 26 or 14 weeks, respectively. FMD and biochemical assessment were performed before and after the treatment periods, and all FMD measurements were conducted under controlled conditions by a well-trained technician who was blinded to the study to minimize the introduction of potential confounding variables. For FMD, neither sitagliptin nor liraglutide affected endothelial cell function in this treatment periods, and neither did glimepiride and glargine (**Table 2**). Some previous clinical trials suggested that GLP-1 analogues and DPP-4 inhibitors improved FMD,¹⁸⁻²⁰ but there is some controversy including the lack of a control group, the study duration, the subject populations, and FMD measurement accuracy. Assessment of FMD is so sensitive that the results were greatly affected by many internal and

environmental factors, such as patients' background (sex, age, obesity, heart rate and smoking),²¹ conditions (air temperature, mental/physical stress),²²⁻²⁴ and the medications described above. There were opposing results and opinions about the relationship between incretin agents and FMD results.^{25,26} Our studies fully controlled these confounding factors and both treatment groups were similarly controlled for glycemic metabolism. Moreover, another assessment method for endothelial dysfunction, End-PAT, also showed the same results. A recent meta-analysis revealed that efficacy of GLP-1-based therapies on FMD was confirmed only in cross-sectional studies but not in longitudinal studies.¹³ It was reported that native GLP-1 infusion for several hours to individuals with type 2 diabetes resulted in improvement in endothelial function.^{27,28} Although both GLP-1 and cleaved GLP-1, such as GLP-1(9-36) and GLP-1(28-36), may cause these effects, a study comparing the effect of native GLP-1 on vascular function with or without of sitagliptin to prevent an increase of the cleaved form of GLP-1 resulted in no detectable changes in both groups.²⁹ Although the existence of the GLP-1 receptor on the vascular endothelium has been suggested, recent accumulating evidence showed that the endothelium does not possess the GLP-1 receptor,^{30,31} but there is currently no consensus. Thus, beneficial effects of incretin-related therapy on atherosclerotic changes may be mainly explained by indirect mechanisms rather than by direct action on endothelial cells.

EFFECTS ON BETA-CELL FUNCTION AND ATHEROSCLEROSIS

Incretin-related agents exert glucose-lowering effects in a blood glucose-dependent manner,³² and they also play an important role in avoiding hypoglycemia by diminishing insulin secretion and preventing glucagon secretion under normal-to-hypoglycemic conditions.³³ Numerous *in vitro* and animal model experiments verified protective and proliferative effects of incretin-related agents on pancreatic beta-cells, and our prospective studies also demonstrated that both a DPP-4 inhibitor and a GLP-1 analogue showed incremental beta-cell functions, assessed by surrogate markers of insulin secretion (**Table 2**). Similarly, some clinical trials using incretin agents clarified incremental beta-cell function.^{34,35} Effects of a GLP-1 analogue on beta-cell signaling include activating adenylate cyclase/protein kinase A, phosphatidylinositol 3-kinase/Akt, and the adenosine monophosphate kinase/mTOR cascades, which results in proliferation of beta-cells in rodents. However, the precise signaling of GLP-1 analogues has not been fully determined in humans.³⁶ Additionally, pancreatic beta-cells are known to be sensitive to oxidative stresses that result from relatively low expression levels of anti-oxidant enzymes, such

Table 1: Inclusion criteria and outline of the original studies

	SAIS-1	SAIS-2
Primary endpoint	Change in flow-mediated dilation.	
Design	Multicenter, prospective, randomized, parallel-group	
Age (years)	20 to 75	20 to 70
Number of patients	110	30
HbA1c (%)	6.9 to 8.4	7.4 to 10.5
Previous treatment	Metformin or none	Metformin and/or Sulphonylurea
Treatment arms	Sitagliptin 50 mg/day or Glimepiride 0.5–2.0 mg/day	Liraglutide 0.9 mg/day or Insulin glargine
Treatment periods (weeks)	26	14

Note: HbA1c: Hemoglobin A1c; SAIS-1: Sapporo athelo-incretin study-1; SAIS-2: Sapporo athelo-incretin study-2.

Table 2: Summary of the original studies

Levels of HbA1c	SAIS-1		SAIS-2	
	Sitagliptin	Glimepiride	Liraglutide	Glargine
%FMD	↓ (Improved)	↓ (Improved)	↓ (Improved)	↓ (Improved)
Inflammatory markers (TNF- α , d-ROMs)	↓ (Improved)	→	↓ (Improved)	→
Anti-oxidant responses (SOD, BAP)	↑ (Improved)	→	→	→
Lipid profiles (adiponectin, HDL-C)	↑ (Improved)	→	→	→
Beta-cell functions (SUIT, C-peptide index)	↑ (Improved)	↑ (Improved)	↑ (Improved)	→
Cardiovascular markers (AI, NT-proBNP)	→	→	↓ (Improved)	→

Note: HbA1c: Hemoglobin A1c; SAIS-1: Sapporo athelo-incretin study-1; SAIS-2: Sapporo athelo-incretin study-2; FMD: flow-mediated dilation; TNF- α : tumor necrosis factor alpha; d-ROMs: reactive oxygen metabolites-derived compounds; SOD: superoxide dismutase; BAP: biological antioxidant potential; HDL-C: high-density lipoprotein cholesterol; SUIT: secretory units of islets in transplantation; AI: augmentation index; NT-proBNP: N-terminal pro-brain natriuretic peptide.

as superoxide dismutase, catalase, and glutathione peroxidase.³⁷ GLP-1 exerts anti-oxidant effects via suppression of nitric acid synthase expression in pancreatic beta-cells.³⁸ DPP-4 inhibitors were reported to reduce apoptosis in pancreatic beta-cells^{39,40} and induce anti-oxidant responses,⁴¹ and such mechanisms might be beneficial for protection of beta-cells from some kinds of stresses.

In addition, long-term administration of these agents showed favorable effects on anti-oxidant, anti-atherosclerotic, and lipid metabolism in our study. One of the DPP-4 inhibitors, sitagliptin, ameliorated HDL-cholesterol via increasing adiponectin, anti-oxidant responses, and serum TNF- α levels. However, the GLP-1 analogue, liraglutide, caused a reduction of oxidative stress and improvement in cardiac load and atherosclerosis (**Table 2**). Incretin-related drugs including DPP-4 inhibitors have been shown to have favorable effects on atherosclerosis *via* mediating several pathways, attenuating TNF- α -mediated induction of plasminogen activator inhibitor-1 expression,⁴² preventing reactive oxygen species-induced cell senescence in endothelial cell lines,⁴³ increasing serum adiponectin lev-

els,⁴⁴ suppressing macrophage-related inflammation, and inhibiting DPP-4-induced smooth muscle proliferation.⁴⁵

Despite these many favorable mechanisms, many clinical trials using DPP-4 inhibitors failed to show their superiority to placebo in CVD outcomes.¹⁰⁻¹² One of the possible reasons is that these trials mainly included patients with atherosclerotic diseases. Therefore, even such potent agents may not be enough to suppress advanced atherosclerotic diseases. Earlier intervention may be beneficial for patients with early-phase atherosclerosis.

CONCLUSIONS

Accumulating evidence suggests that incretin-based therapy has anti-atherosclerotic effects and favorable effects on pancreatic beta-cells. However, the long-term results on endothelial cell function have not yet been determined. Our clinical trials provided direct evidence that these agents did not improve endothelial cell function in patients with type 2 diabetes, although their favorable effects on beta-cells and atherosclerosis are expected and will be assessed in the future.
