Abbreviation

AOC, allene oxide cyclase; AOS, allene oxide synthase; COI1, coronatine insensitive 1; 12,13-EOT, (9*Z*,15*Z*)-(13*S*)-12,13-epoxyoctadeca-9,11,15-trienoic acid; GC-MS, gas chromatography-mass spectrometry; 13-HPOT, 13-hydroperoxyoctadecatrienoic acid; IPTG, isopropyl β–D-1-thiogalactopyranoside; JA, jasmonic acid; JA-Ile, jasmonoyl-isoleucine; JAR1, jasmonic acid resistant 1; JAZ, jasmonate-zim domain; LOX, lipoxygenase; Ni-NTA, nickel-nitrilotriacetic acid; OPC-8:0, 3-oxo-2-(*cis*-2'-pentenyl)cyclopentane-1-octanoic acid; OPDA, 12-oxo-phytodienoic acid; OPR, 12-oxo-phytodienoic acid reductase; SCF, skp-cullin-F box; SDS-PAGE, sodium dodecyl sulfate-polyacrylamide gel electrophoresis; UPLC-MS/MS, ultra-performance liquid chromatography-tandem mass spectrometry

Abstract

Jasmonic acid (JA) is involved in a variety of physiological responses in seed plants. However, the detection and role of JA in lycophytes, a group of seedless vascular plants, have remained elusive until recently. This study provides the first evidence of 12-oxo-phytodienoic acid (OPDA), JA, and jasmonoyl-isoleucine (JA-Ile) in the model lycophyte *Selaginella moellendorffii*. Mechanical wounding stimulated the accumulation of OPDA, JA, and JA-Ile. These data were corroborated by the detection of enzymatically active allene oxide synthase (AOS), allene oxide cyclase (AOC), 12-oxo-phytodienoic acid reductase 3 (OPR3), and JA-Ile synthase (JAR1) in *S. moellendorffii*. SmAOS2 is involved in the first committed step of JA biosynthesis. SmAOC1 is a crucial enzyme for generating the basic structure of jasmonates and is actively involved in the formation of OPDA. SmOPR5, a functionally active OPR3-like enzyme, is also vital for the reduction of (+)-*cis*-OPDA, the only isomer of the JA precursor. The conjugation of JA to Ile by SmJAR1 demonstrates that *S. moellendorffii* produces JA-Ile. Thus, the four active enzymes have characteristics similar to those in seed plants. Wounding and JA treatment induced the expression of *SmAOC1* and *SmOPR5*. Furthermore, JA inhibited the growth of shoots in *S. moellendorffii*, which suggests that JA functions as a signaling molecule in *S. moellendorffii*. This study proposes that JA evolved as a plant hormone for stress adaptation, beginning with the emergence of vascular plants.

Keywords

AOS; AOC; JAR1; Jasmonic acid; OPR3; *Selaginella moellendorffii*

Introduction

As sessile organisms, plants must adapt to many environmental stresses that can negatively affect their development, growth, productivity, and fertility by altering their physiological, morphological, and/or developmental processes. Many studies have found that JA modulates numerous plant physiological processes that are related to development and defense responses (Wasternack and Parthier 1997, Ziegler et al. 2000, Ishiguro et al. 2001, Wasternack 2007). Indeed, JA is a naturally occurring phytohormone that is ubiquitous in seed plant species (Creelman and Mullet 1997).

The JA biosynthetic pathway (Fig. 1) starts with the lipase-mediated release of α-linolenic acid from the membrane lipids of chloroplasts (Wasternack and Hause 2013), which is triggered by abiotic and biotic stresses (Farmer and Ryan 1992, Mueller et al. 1993, Conconi et al. 1996, Penninckx et al. 1996, Narváez-Vásquez et al. 1999). In chloroplasts, α-linolenic acid is converted into 13(*S*)-hydroperoxyoctadecatrienoic acid [13(*S*)-HPOT]; this process is mediated by 13-lipoxygenase (13-LOX). The 13(*S*)-HPOT intermediate can be dehydrated through the action of allene oxide synthase (AOS), which leads to JA biosynthesis (Yan et al. 2013). In the presence of AOS, the dehydration of the resultant fatty acid hydroperoxide forms an allene oxide (12,13-EOT), which is then cyclized by allene oxide cyclase (AOC) into *cis*-(+)-12-oxo-phytodienoic acid [(9*S*,13*S*)-OPDA]. The specificity of AOC determines the configuration of the side chains in the naturally occurring structure of jasmonates. The resulting OPDA is then transferred into peroxisomes, where OPDA reductase 3 (OPR3) reduces *cis*-(+)-OPDA to 3-oxo-2-(*cis*-2'-pentenyl)cyclopentane-1-octanoic acid (OPC-8:0), which is then converted into (+)-7-*iso*-JA through three β-oxidation steps. Subsequently, (+)-7-*iso*-JA is isomerized to (−)-JA and released into the cytoplasm via an unknown mechanism (Ziegler et al. 2000, Hyun et al. 2008,

88 Khan et al. 2012). JA can be enzymatically converted into many derivatives, such as methyl
89 jasmonate and JA-amino acid conjugates. The jasmonic acid resistant 1 (*JAR1*) gene encodes the
90 enzyme that is responsible for the conjugation of JA to amino acids, i.e., isoleucine and valine.
91 Among these conjugates, JA-Ile is considered to be an important compound in the JA signaling
92 pathway (Stenzel et al. 2012). Under stress conditions, the JA-Ile level increases, and JA-Ile
93 binds to its receptor, COI1, a component of the SCF complex. Subsequently, JA-Ile mediates the
94 initial binding of the JAZ protein to the COI1-JA-Ile unit of the SCF complex, which results in
95 degradation by the 26S proteasome and the release of MYC2 (Fonseca et al. 2009a, 2009b,
96 Sheard et al. 2010, Santino et al. 2013).

97 Vascular plants have survived on earth for the past 420 million years and have diverged
98 into several descendants. Only two descendants have survived: the euphyllophytes and
99 lycophytes (Kenrick and Crane 1997, Banks et al. 2011). Fossil evidence shows that lycophytes
100 diverged shortly after land plants evolved vascular tissues, which generated all other vascular
101 plants. There are currently only three extant lycophyte groups: the Lycopodiales (club mosses),
102 Isoetales (quillworts), and Selaginellales (spike mosses) (Weng et al. 2005, Banks 2009, Hecht et
103 al. 2011). Recently, the approximately 100 Mbp genome of *Selaginella moellendorffii* was fully
104 sequenced (Banks et al. 2011). This model lycophyte, as a representative of the earliest and still
105 surviving vascular plant lineage, can potentially provide information for deciphering the
106 evolution of the physiological, biochemical, and developmental processes that are unique to land
107 plants.

108 The model plants that transitioned from water to land, such as the moss *Physcomitrella*
109 *patens* and the liverwort *Marchantia polymorpha*, produce OPDA but not JA (Stumpe et al. 2010,
110 Yamamoto et al. 2015). These findings strongly suggest that the first half of the octadecanoid

111 pathway in chloroplasts remains in bryophytes. Thereafter, the difference in JA production
112 between seed plants and bryophytes is one of the significant observations in the study of plant
113 evolution. The lycophytes are intermediate plants between bryophytes and seed plants, and this
114 ancient lineage diverged shortly after land plants evolved vascular tissues. Thus, the origin of JA
115 is of interest for studying plant evolution. In this study, we analyzed the lycophyte model *S.*
116 *moellendorffii* to determine the presence of OPDA, JA, and JA-Ile, as well as the enzymatic
117 activities of AOS, AOC, OPR3, and JAR1, which are involved in the biosynthesis of jasmonates.
118 Moreover, we showed the growth inhibitory activity of OPDA, JA, and JA-Ile in *S.*
119 *moellendorffii*. These data indicate a possible role for JA as a signaling molecule that regulates
120 growth and response to wounding in *S. moellendorffii.*
121
122 **Results**
123 *Identification of OPDA, JA, and JA-Ile in S. moellendorffii*
124 Seed plants can biosynthesize JA and JA-Ile; however, these compounds are absent in the model
125 bryophytes *P. patens* and *M. polymorpha* (Stumpe et al. 2010, Yamamoto et al. 2015). In this
126 study, we evaluated *S. moellendorffii*, which belongs to a lycophyte group that is taxonomically
127 positioned between bryophytes and euphyllophytes, to identify JA and its related compounds. We
128 detected OPDA, JA, and JA-Ile in *S. moellendorffii* using ultra-performance liquid
129 chromatography tandem mass-spectrometry (UPLC-MS/MS) analysis (Fig. 2). The OPDA
130 analytical data revealed a predominant peak in the chromatogram of an *S. moellendorffii* extract
131 (*m/z* 164.99 derived from the peak at *m/z* 291.37 $[M-H]^-$; Figs. 2A, 2B, and 2C). This peak
132 overlapped with the *cis*-OPDA standard peak, which indicates that OPDA is present in *S.*
133 *moellendorffii*. The minor peak that eluted before *cis*-OPDA was speculated to be either an

unidentified OPDA-related compound or a *trans*-isomer of OPDA (Fig. 2B). The analytical JA data clearly demonstrated that the standard JA peak overlapped with the peak derived from an extract of *S. moellendorffii* (*m/z* 58.71 derived from the peak at *m/z* 209.09 $[M-H]^-$; Figs. 2D, 2E, and 2F). This result indicated the presence of JA in *S. moellendorffii.* Furthermore, an analysis of JA-Ile showed that the retention time of standard JA-Ile was the same as that of the peak derived from an extract of *S. moellendorffii* (*m/z* 129.68 derived from the peak at *m/z* 323.03 $[M-H]^-$; Figs. 2G, 2H, and 2I), suggesting that *S. moellendorffii* also biosynthesizes JA-Ile. The minor peak that was detected in the extract is potentially an unidentified contaminant that was not further analyzed (Fig. 2H). These data are the first evidence of OPDA, JA, and JA-Ile in *S. moellendorffii*.

Accumulation of OPDA, JA, and JA-Ile upon wounding stress

JA plays important roles in stress adaptation. Therefore, the accumulation of JA is considered a response to adverse environmental conditions involving both biotic and abiotic stresses, especially in seed plants (Wasternack and Hause 2013). Wounding activates the octadecanoid pathway, which results in the accumulation of OPDA, JA, and JA-Ile in seed plants. To illustrate the response of *S. moellendorffii* to wounding stress, the photosynthesizing organs (stems and microphylls) were mechanically wounded and then analyzed at different time points. The endogenous levels of OPDA, JA, and JA-Ile were analyzed using UPLC-MS/MS (Fig. 3). *S. moellendorffii* transiently produced a high level of OPDA within the first 10 min after wounding. OPDA was approximately 200-fold more abundant than JA at 10 min after wounding, whereas the JA level peaked at 30 min, following the initial increase at 10 min. In contrast to the rapid increase in the OPDA and JA concentrations, JA-Ile accumulation was delayed and started at 180

157 min after wounding. The increased levels of JA and JA-Ile were accompanied by a rapid decrease
158 in the OPDA concentration. These data revealed that wounding increased the endogenous levels
159 of these jasmonates in *S. moellendorffii*, similar to the response in seed plants. Accordingly,
160 environmental stress probably activates the octadecanoid pathway. OPDA, JA, and JA-Ile also
161 seem to play a role in regulating the response to wounding in *S. moellendorffii.*
162
163 *Putative AOS, AOC, OPR3 and JAR1 genes in S. moellendorffii*
164 To further confirm the presence of OPDA, JA, and JA-Ile in *S. moellendorffii*, we
165 investigated the characteristics of important JA biosynthetic enzymes in *S. moellendorffii*. A
166 genomic database analysis using Phytozome v 11.0
167 (https://phytozome.jgi.doe.gov/pz/portal.html) was performed to screen *AOS*, *AOC*, *OPR3*, and
168 *JAR1* homologous genes in *S. moellendorffii* using *Arabidopsis* amino acid sequences
169 corresponding to these proteins as queries. As a result, the presence of putative *AOS* (*SmAOS1*,
170 Sm_271334; *SmAOS2*, Sm_177201; *SmAOS3*, Sm_228572), *AOC* (*SmAOC1*, Sm_91887), *OPR3*
171 (*SmOPR1*, Sm_270843; *SmOPR5*, Sm_111662), and *JAR1* (*SmJAR1*, Sm_110439) genes was
172 predicted in *S. moellendorffii* (Supplementary Table S1).
173
174 *Functional analysis of SmAOS2*
175 The first committed step of JA biosynthesis is catalyzed by AOS, which converts 13-HPOT
176 into unstable 12,13-EOT. A genomic database analysis of Phytozome v 11.0 revealed the
177 presence of nine putative *AOS* genes in *S. moellendorffii*. Amino acid sequence analysis of the
178 SmAOS candidates showed that SmAOS1, SmAOS2, and SmAOS3 were promising candidates
179 containing the important sequence motifs: the I-helix GXXX (F/L), EXLR motif, and heme-

180 binding PXVXNKQCPG, which are characteristic of members of the CYP74 family
181 (Supplementary Fig. S1) (Koeduka et al. 2015). Additionally, the amino acid sequences of
182 SmAOS1, SmAOS2, and SmAOS3 are quite similar (Supplementary Fig. S1). A phylogenetic
183 tree of the AOSs showed that the SmAOSs were separated from the seed plant AOSs
184 (Supplementary Fig. S2). Computational analysis using ChloroP v 1.1
185 (http://www.cbs.dtu.dk/services/ChloroP/) and iPSORT (http://ipsort.hgc.jp/) for subcellular
186 localization predicted the absence of a transit peptide in SmAOS1, SmAOS2, and SmAOS3,
187 whereas most known AOSs are localized in chloroplasts (Schaller and Stintzi 2009).

188 To confirm AOS activity in this plant, the production of these recombinant SmAOSs was
189 attempted. However, only recombinant SmAOS2 fused with a His-tag was successfully
190 synthesized in *E. coli*. Purification of recombinant SmAOS2 by Ni-NTA affinity column
191 chromatography and SDS-PAGE analysis revealed a clear band of SmAOS2 with an expected
192 molecular weight of approximately 50 kDa (Supplementary Fig. S3). The AOS reaction converts
193 13(*S*)-HPOT to unstable 12,13-EOT, which is non-enzymatically changed to racemic OPDA.
194 Therefore, AOS enzymatic activity can be determined by analyzing the presence of racemic
195 OPDA. The recombinant SmAOS2 was incubated with 13(*S*)-HPOT, and then the products were
196 extracted with ethyl acetate, followed by isomerization by alkaline treatment and methylation
197 using ethereal diazomethane. Laudert et al. (1997) demonstrated that chiral GC-MS analysis of
198 methylated OPDA can clearly separate the *trans*-isomers of methylated OPDA; therefore,
199 isomerization was performed to convert *cis*-OPDA to *trans*-OPDA. Peaks of methylated (+)-
200 *trans*-OPDA and methylated (−)-*trans*-OPDA were both identified in the SmAOS2 reaction
201 products on the chiral GC-MS chromatogram (Fig. 4). Furthermore, an ion peak at *m/z* 306,
202 corresponding to the molecular ion peak $[M]^+$ of OPDA methyl ester, was observed together with

unique fragment ion peaks at *m/z* 275 ($[M-OCH_3]^+$), *m/z* 238 ($[M-C_5H_9]^+$), and *m/z* 149 ($[M-C_9H_{17}O_2]^+$) in the GC-MS spectral data of both methylated (+)-*trans*-OPDA and methylated (−)-*trans*-OPDA (Supplementary Figs. S4S6, Laudert et al. 1997). These results showed that SmAOS2 had AOS activity similar to that of previously characterized AOSs.

Functional analysis of SmAOC1

AOC has been successfully cloned from seed plants, a moss, and a liverwort (Ziegler et al. 2000, Agrawal et al. 2003, Stenzel et al. 2003, Maucher et al. 2004, Farmaki et al. 2007, Pi et al. 2008, Stumpe et al. 2010, Hashimoto et al. 2011, Yamamoto et al. 2015). The 5'-UTR of *SmAOC1* was examined by 5'-RACE to obtain the full-length sequence. A computational analysis using ChloroP v 1.1 and iPSORT predicted that SmAOC1 has a chloroplast transit peptide at its N-terminus. The amino acid sequence alignment of SmAOC1 and AOCs of other plants showed that SmAOC1 had high similarity to other AOCs (Supplementary Fig. S7). The phylogenetic tree of AOCs demonstrated that SmAOC1 was related to MpAOC from the liverwort *M. polymorpha* and to AOCs in seed plants, while it was separated from PpAOC1 and PpAOC2 of the moss *P. patens* (Supplementary Fig. S8).

To determine whether SmAOC1 is involved in the production of OPDA, *SmAOC1* was cloned and overexpressed in *E. coli*. The recombinant SmAOC1 was fused with a His-tag at the N-terminus to replace the chloroplast signal peptide. After purifying SmAOC1 using Ni-NTA affinity column chromatography, a protein with the expected size of 22 kDa was clearly detected as a single band by SDS-PAGE analysis (Supplementary Fig. S3). The purified recombinant SmAOC1 was used for enzymatic analysis.

225 Due to the instability of 12,13-EOT, which is the substrate for the AOC reaction, the
226 enzymatic activity of SmAOC1 was tested in a reaction mixture containing SmAOC1, PpAOS1,
227 and 13(*S*)-HPOT as substrates. For a negative control, only PpAOS1 and 13(*S*)-HPOT were used
228 in a reaction mixture. After terminating the reaction, the resulting *cis*-OPDA product was
229 converted to *trans*-OPDA by alkaline treatment, which was followed by methylation using
230 ethereal diazomethane. *Trans*-OPDA was finally analyzed by chiral GC-MS. The molecular ion
231 peak of the OPDA methyl ester at *m/z* 306 $[M]^+$ was monitored to evaluate SmAOC1 activity
232 (Laudert et al. 1997) (Fig. 5). The GC-MS analysis showed a predominant molecular ion peak (ca.
233 97%) in the reaction mixture containing SmAOC1. The retention time of this peak coincided with
234 the standard *trans*-(+)-OPDA methyl ester, which represents *cis*-(+)-OPDA. In contrast, two
235 molecular ion peaks of the racemic *trans*-OPDA methyl esters were detected in the product of the
236 PpAOS1 reaction. This result demonstrated that SmAOC1 converts 12,13-EOT into *cis*-(+)-
237 OPDA, similar to previously reported AOCs.
238 The first of three enzymes involved in JA biosynthesis (LOX, AOS, and AOC) have been
239 reported to reside in chloroplasts (Schaller and Stintzi, 2009). To examine whether SmAOC1 is
240 localized in chloroplasts, a 35S::SmAOC1-GFP plasmid was constructed and introduced into *P.*
241 *patens* protoplasts and was then finally observed by confocal laser scanning microscopy. The
242 green fluorescent signal of SmAOC1 fused with GFP was clearly identified by the red auto-
243 fluorescence of chlorophyll. The overlay data also strongly supported that SmAOC1 is located in
244 chloroplasts, which is similar to the other characterized AOCs (Supplementary Fig. S9).
245 Accordingly, chloroplast could be the functional organelle in the biosynthesis of OPDA in *S.*
246 *moellendorffii*.
247

248 *Functional analysis of SmOPRs*

249 OPRs are classified into two groups based on their ability to reduce OPDA: OPR3-like
250 enzymes (e.g., *Arabidopsis* AtOPR3, tomato SlOPR3, and rice OsOPR7) and OPR1-like enzymes
251 (e.g., AtOPR1 and SlOPR1) (Breithaupt et al. 2009). OPR3-like enzymes catalyze the reduction
252 of *cis*-(+)-OPDA, a natural JA precursor, and of *cis*-(−)-OPDA, which is not involved in JA
253 biosynthesis. The *Arabidopsis opr3* mutant shows male sterility and is desensitized to responses
254 involving JA signaling. In contrast, OPR1-like enzymes preferentially reduce *cis*-(−)-OPDA
255 rather than *cis*-(+)-OPDA; therefore, OPR1-like enzymes might function in pathways other than
256 JA biosynthesis.

257 A genomic database search using Phytozome v 11.0 predicted the presence of six putative
258 *OPR* genes in *S. moellendorffii*. All of the amino acid sequences of candidate SmOPRs were
259 aligned with those of other known OPRs (Supplementary Fig. S10). Based on a comparison of
260 two critical amino acids for substrate binding and a phylogenetic analysis of SmOPRs
261 (Supplementary Fig. S10), two genes designated *SmOPR1* and *SmOPR5* were highly promising
262 candidate genes that encoded OPR3-like enzymes involved in JA biosynthesis. SmOPR1 harbors
263 two important active-site residues, Phe and His, as an OPR3 motif in the active site, which is
264 considered to be necessary to reduce the JA precursor *cis*-(+)-OPDA. However, SmOPR1 was
265 grouped with the other SmOPRs in an independent OPR cluster (Supplementary Fig. S11). In
266 contrast, SmOPR5 was a member of the cluster of OPR3-like enzymes, such as AtOPR3,
267 OsOPR7, SlOPR3, ZmOPR7, and ZmOPR8, which are active in JA biosynthesis (Supplementary
268 Fig. S11). Moreover, SmOPR5 shared 53% amino acid sequence identity with AtOPR3.
269 Nonetheless, instead of Phe and His, which are considered unique to the OPR3 substrate filter,

the active site residues of SmOPR5 were Trp and His. Therefore, these two genes were selected for further analysis to verify their enzymatic activity.

To confirm the enzymatic activities, recombinant SmOPR1 and SmOPR5 proteins fused with a His-tag were produced in *E. coli*. SDS-PAGE analysis showed that the recombinant SmOPR1 and SmOPR5 appeared as single bands with an expected molecular weight of approximately 40 kDa (Supplementary Fig. S3). The enzymatic reactions were conducted according to the method of Schaller et al. (1998) with some modifications. Recombinant SmOPR1 and SmOPR5 were incubated in 50 mM potassium phosphate buffer (pH 7.4) containing NADPH and *cis*-(±)-OPDA. After terminating the OPR reactions, the *cis*-isomers of OPDA and OPC-8:0 in the OPR reaction solutions were converted into *trans*-isomers of OPDA and OPC-8:0 by alkaline treatment. The reaction products were finally analyzed by chiral GC-MS after methylation (Vick and Zimmerman 1983, Laudert et al. 1997). In the GC-MS chromatogram of SmOPR1 reaction products, only the peak of methylated *trans*-(−)-OPC-8:0, which was derived from the non-JA precursor *cis*-(−)-OPC-8:0, appeared; there was no peak for methylated *trans*-(+)-OPC-8:0, which was derived from *cis*-(+)-OPDA, a natural JA biosynthetic intermediate (Fig. 6). Therefore, SmOPR1 did not participate in JA biosynthesis. In contrast, SmOPR5 catalyzed the reduction of both *cis*-(±)-OPDA enantiomers to both (±)-OPC-8:0 enantiomers (Fig. 6). The fragmentation of methylated *trans*-(+)-OPC-8:0 (Peak 1) derived from *cis*-(+)-OPDA was similar to that of standard methylated OPC-8:0 (Supplementary Figs. S12 and S13). These data indicated that *SmOPR5* encodes a functional OPR3 that participates in JA biosynthesis in *S. moellendorffii.*

Enzymatic production of JA-Ile by SmJAR1

JA-Ile is a versatile signaling molecule for JA-mediated defense and developmental events and is produced by the conjugation of JA and Ile. JAR1s are GH3 proteins that have the ability to synthesize JA-Ile (Staswick and Tiryaki 2004). An *Arabidopsis jar1* mutant, which is unable to produce JA-Ile, fails to trigger JA-mediated responses (Suza and Staswick 2008). Thus, JAR1 activity is necessary for JA signal transduction in seed plants. Here, we found 14 *JAR1* homologous genes in the Phytozome database using AtJAR1 as a query (Supplementary Table S1). Multiple sequence alignment and phylogenetic analysis using Clustal Omega software were performed to show the relationship between these JAR1 homologous proteins in *S. moellendorffii* and the other existing JAR1 proteins (Supplementary Figs. S14 and S15). As a result, the candidate Sm_110439, which was designated SmJAR1, was most closely related to AtJAR1, OsJAR1 and OsJAR2, which can synthesize JA-Ile (Staswick and Tiryaki 2004, Wakuta et al. 2011). Moreover, SmJAR1 also has three short conserved motifs involved in ATP/AMP binding (Chang et al. 1997): SSGTSQGRPK (motif 1), YGSSE (motif 2), and YRLGD (motif 3) (Supplementary Fig. S14). To determine whether *SmJAR1* encodes functional JA-Ile synthase in *S. moellendorffii*, *SmJAR1* was isolated to check its enzymatic activity.

To evaluate JAR1 activity, *E. coli* expressing *SmJAR1* were incubated with (−)-JA as a substrate. JA-Ile in the culture supernatant of *E. coli* was analyzed by UPLC-MS/MS. The analytical data clearly showed that SmJAR1 catalyzes the conjugation of JA to Ile using endogenous ATP and Ile in *E. coli* (Fig. 7). To investigate the substrate specificity of SmJAR1, the conjugation of JA to other amino acids was also analyzed. No peak derived from another conjugate of JA-Trp, JA-Phe, or JA-Val appeared in the culture supernatant of *E. coli* expressing *SmJAR1* (Supplementary Fig. S16). Therefore, SmJAR1 was hypothesized to prefer Ile for conjugation with JA.

315

316 *Expression of genes encoding key enzymes in JA-Ile biosynthesis under wounding stress and JA*
317 *treatment*

318 Wounding and JA induce the expression of a wide variety of genes in seed plants, such as
319 defense-related genes, and genes encoding enzymes involved in JA biosynthesis. To determine if
320 wounding and JA treatment affect gene expression in *S. moellendorffii*, quantitative RT-PCR
321 analysis was performed to analyze the expression of *SmAOC1*, *SmOPR5*, and *SmJAR1*.
322 Wounding increased the transcription levels of *SmAOC1*, *SmOPR5*, and *SmJAR1* (Fig. 8). The
323 expression of *SmAOC1* was transiently induced at 10 min after wounding and then decreased
324 until 180 min. The accumulation of *SmOPR5* mRNA reached a maximum 20 min after wounding
325 and decreased thereafter. By contrast, only weak expression was observed for *SmJAR1* until 60
326 min, followed by an increase in *SmJAR1* expression at 180 min. These results indicate that the
327 expression kinetics of *SmAOC1, SmOPR5,* and *SmJAR1* coincided with the accumulation profiles
328 of OPDA, JA, and JA-Ile in wounded *S. moellendorffii*.

329 The analytical data on *SmAOC1* and *SmOPR5* expression in JA-treated *S. moellendorffii*
330 revealed an initial increase in transcription levels in the first 30 and 10 min, respectively, after JA
331 treatment (Fig. 9). The accumulation of *SmAOC1* continued to increase until 60 min after JA
332 application and decreased thereafter, whereas the transcription level of *SmOPR5* decreased 30
333 min after treatment. The expression profiles of *SmAOC1* and *SmOPR5* in the plants treated with
334 JA were similar to those in the wounded plants. In contrast to *SmAOC1* and *SmOPR5*, the
335 expression of *SmJAR1* was suppressed within 10 min after JA treatment and remained at a low
336 level thereafter.

337

Effect of exogenous OPDA, JA, and JA-Ile on the growth of S. moellendorffii shoots

Growth inhibition caused by JA is one of the most significant physiological responses in seed plants. To examine the ability of OPDA, JA, and JA-Ile to inhibit the growth of *S. moellendorffii*, bulbils of *S. moellendorffii* (Supplementary Fig. S17) were sprinkled onto soil, and the germinated plants were grown with or without treatment with OPDA, JA, or JA-Ile at concentrations of 25, 50, and 100 μM. After four weeks, the lengths of the shoots of *S. moellendorffii* were measured. All jasmonates tested in this study were shown to have growth inhibitory effects on shoots of *S. moellendorffii* (Fig. 10, supplementary Fig. 18). Both OPDA and JA inhibited growth in a dose-dependent manner, with a stronger effect with OPDA than with JA. JA-Ile also retarded the growth of the shoots of this plant, but the growth inhibitory effect did not increase with increasing concentrations of JA-Ile. This is the first report that OPDA, JA, and JA-Ile inhibit the growth of seedless vascular plants, such as lycophytes.

Discussion

Identification and accumulation of OPDA, JA, and JA-Ile

In this study, the presence of OPDA, JA, and JA-Ile in *S. moellendorffii* was successfully demonstrated (Fig. 2). Moreover, wounding transiently increased the endogenous concentrations of OPDA and JA in *S. moellendorffii* within 10 min (Fig. 3), which is probably due to the role of jasmonates in regulating responses to environmental stress in S. *moellendorffii*. Given that wounding also stimulated OPDA and JA in the fern *Pteridium aquilinum* (Radhika et al. 2012), the accumulation of JA in response to wounding is likely a common physiological response among all vascular plant species (Maucher et al. 2004). However, JA-Ile accumulated more slowly than OPDA and JA after wounding. It is possible that the early rise in JA levels within 30

361 min represents an early response, whereas the slow JA-Ile accumulation may be attributable to a
362 late stress response in this plant.

363 The transient increases in JA and OPDA after wounding observed in *S. moellendorffii* are
364 similar to those observed in seed plants. It has been suggested that another metabolic pathway is
365 required to inactivate JA responses in *S. moellendorffii*. In *Arabidopsis*, the oxidation of JA-Ile,
366 which decreases the JA-Ile concentration, is important for regulating JA activity (Kitaoka et al.
367 2011, Koo et al. 2011). A phylogenetic analysis of cytochrome P450s in *A. thaliana*, *P. patens*,
368 and *S. moellendorffii* revealed that SmCYP94Js (SmCYP94J1, SmCYP94J2, SmCYP94J3,
369 SmCYP94J5Pv1, and SmCYP94J5Pv2) are members of a cluster that includes AtCYP94B3 and
370 AtCYP94C1 as enzymes responsible for the oxidation of JA-Ile and 12OH-JA-Ile (Banks et al.
371 2011). SmCYP94Js are likely related to the oxidation of JA-Ile, leading to the inactivation of JA
372 activity.

373 In studies of *P. patens* and *M. polymorpha*, only OPDA has been detected in both plants
374 (Stumpe et al. 2010, Yamamoto et al. 2015). In contrast to vascular plants, JA is not important for
375 the physiology of these model bryophytes. Hence, our data suggest that JA and JA-Ile
376 biosynthesis first appeared after bryophytes in plant evolution (Figs. 2 and 3). Additionally, there
377 is a significant difference between bryophytes and lycophytes. Lycophytes have a vascular
378 system for the efficient transport of water, nutrients, and molecules, as well as for enhancing
379 plant height and size. It is likely that the emergence of the JA biosynthetic pathway after OPDA
380 is related to the acquisition by plants of a vascular system.

381

382 *Enzymatic activity*

383 There have been no previous studies on enzymes in the JA biosynthetic pathway of non-seed
384 vascular plants. To support the analytical data showing the presence of OPDA, JA, and JA-Ile,
385 the enzymatic activities of AOS, AOC, OPR3, and JAR1 were investigated. Here, genes
386 encoding functional AOS, AOC, OPR3, and JAR1 proteins (SmAOS2, SmAOC1, SmOPR1 and
387 SmOPR5, and SmJAR1, respectively) were identified in *S. moellendorffii*.
388
389 *SmAOS2*. The AOS reaction is the first committed step of JA biosynthesis in plants. AOS is
390 classified as a member of the CYP74 family and requires an oxygenated fatty acid hydroperoxide
391 substrate instead of oxygen or a redox partner (Howe and Schilmiller 2002, Werck-Reichhart et
392 al. 2002). This study revealed three AOS candidate genes (*SmAOS1*, *SmAOS2*, and *SmAOS3*) in *S.*
393 *moellendorffii* (Supplementary Figs. S1 and S2). Among them, recombinant SmAOS2, which
394 was successfully produced in *E. coli*, exhibited AOS activity similar to that of previously
395 reported AOSs (Fig. 4, Supplementary Figs. S4−S6). Computer programs analyzing protein
396 subcellular localization did not predict a transit peptide in the N-terminus of SmAOS2. Because
397 most known AOSs are localized in chloroplasts, SmAOS2 is likely located in chloroplasts for JA
398 biosynthesis. Since the amino acid sequences of SmAOS1, SmAOS2, and SmAOS3 are similar,
399 further investigation is needed to clarify the physiological functions of each of these SmAOSs.
400
401 *SmAOC1*. AOC is a critical enzyme that establishes the enantiomeric structure of OPDA, which
402 contributes to the basic structure of jasmonates. The enzymatic activity of SmAOC1 is required
403 for the synthesis of naturally occurring OPDA (Fig. 5). The stereochemistry of OPDA in *S.*
404 *moellendorffii* is the same as that in other studied plants. Our microscopic observations using
405 SmAOC1 fused to GFP showed that SmAOC1 localized to chloroplasts (Supplementary Fig. S9).

406 These results suggest that the first half of the octadecanoid pathway for synthesizing OPDA is
407 present in the chloroplasts of *S. moellendorffii*. The presence of LOX, AOS, and AOC in
408 chloroplasts may have been conserved during the process of land plant evolution.
409
410 *SmOPR1 and SmOPR5*. The enzymatic analysis of SmOPR1 and SmOPR5 revealed that *S.*
411 *moellendorffii* possesses two types of OPRs that are classified by substrate preference: OPR1-like
412 enzymes and OPR3-like enzymes. SmOPR1 and SmOPR5 are similar in their molecular mass
413 and isoelectric point (pI) (Table 1) but differ in their substrate specificity for *cis*-OPDA isomers.
414 Of these two SmOPRs, only SmOPR5 reduced *cis*-(±)-OPDA, including the endogenous
415 substrate *cis*-(+)-OPDA, which is the natural JA precursor (Fig. 6, Supplementary Figs. S12 and
416 S13). In contrast to SmOPR5, SmOPR1 reduced only *cis*-(−)-OPDA, which is the unnatural type
417 (Fig. 6). SmOPR1 might instead be required for the oxylipin metabolic pathway.
418 A structural comparison of tomato SlOPR1 and SlOPR3 indicated that two active site
419 residues, Tyr78 and Tyr246 in SlOPR1 and Phe74 and His244 in SlOPR3, are critical for
420 substrate specificity (Breithaupt et al. 2009). SlOPR3 is less enantioselective due to its two
421 relatively smaller amino acid residues that form a larger substrate binding pocket. In contrast, the
422 relatively larger amino acids (two Tyr residues) in SlOPR1 permit access to only *cis*-(−)-OPDA,
423 the unnatural type, at the substrate binding site. This study showed that SmOPR5, but not
424 SmOPR1, actively converts the endogenous substrate *cis*-(+)-OPDA to *cis*-(+)-OPC-8:0. This
425 result contrasts with the prediction from the substrate preference analysis of their active site
426 residues but agrees with the phylogenetic analysis of OPRs (Supplementary Figs. S10 and S11).
427 Mutation of the important amino acids Phe and His into Tyr in SlOPR3 did not completely
428 change the substrate specificity (Breithaupt et al. 2009). There is an unidentified factor in the

429 structure of OPRs that is important for substrate specificity, and this factor must be identified by
430 further crystal structure analysis.
431 Li et al. (2009) showed that OPRs from the lower land plants *P. patens* (PpOPR1, PpOPR2,
432 PpOPR4, and PpOPR5) and *S. moellendorffii* (SmOPR1, SmOPR2, SmOPR3, SmOPR4, and
433 SmOPR6) clustered together in subgroup VI. Because SmOPR1 showed OPR1 activity, the other
434 OPRs in subgroup VI may be unrelated to JA biosynthesis. In contrast, the other known OPR3-
435 like enzymes are positioned in the same cluster in subgroup II. It is most likely that OPR3-like
436 enzymes independently evolved to expand the substrate binding pocket to accept *cis*-(+)-OPDA.
437
438 *SmJAR1*. JAR1 is responsible for conjugating JA to amino acids. Because JA-Ile is a versatile
439 molecule in JA signaling, JAR1 is necessary for JA-mediated physiological events in seed plants
440 (Wasternack and Hause 2013). JAR1 is a member of the GH3 proteins, which are classified into
441 three groups based on their enzymatic activity. Group I proteins, such as *Arabidopsis* AtJAR1,
442 can synthesize the JA-amino acid conjugates JA-Ile, JA-Leu and JA-Val (Staswick and Tiryaki
443 2004). Group II proteins conjugate IAA and SA to various amino acids (Staswick et al. 2005).
444 Group III proteins accept benzoates as substrates for amino acid conjugation (Okrent et al. 2009).
445 A group I GH3 protein from seed plants showed JA-Ile synthase activity, which functions in
446 defense (Kang et al. 2006, Wang et al. 2007, Suza et al. 2010).
447 *S. moellendorffii* produces JA-Ile based on evidence of a functionally active SmJAR1 (Fig. 7).
448 The identification of JA-Ile and an active SmJAR1 strongly suggests that JA-Ile-mediated
449 signaling is functional in *S. moellendorffii.* Moreover, SmJAR1 was hypothesized to prefer Ile as
450 a substrate for conjugation with JA (Fig. 7 and Supplementary Fig. S16). The same characteristic
451 was also found in AtJAR1 (Staswick and Tiryaki 2004, Suza and Staswick 2008). Considering

452 the substrate specificity of SmJAR1, JA-Ile seems to be more important than the other JA-amino
453 acid conjugates. Additionally, endogenous conjugates of JA with another amino acid, such as JA-
454 Trp, JA-Phe, JA-Gly, JA-Leu, and JA-Val, have not been found in *S. moellendorffii*
455 (Supplementary Fig. 19).

456 In the case of rice (*Oryza sativa*), OsJAR2 in the cluster of group II GH3 proteins can
457 conjugate JA to Ile, similar to OsJAR1 in the cluster of group I GH3 proteins (Wakuta et al.
458 2011). The other thirteen of JAR1 homologs found in *S. moellendorffii* might also show JA-Ile
459 synthetic activity. Given that GH3 proteins synthesize conjugates of JA and amino acids in *P.*
460 *patens* (Ludwig-Müller et al. 2009), land plants are suggested to have enzymes with ubiquitous
461 JAR1 activity. JA synthesis and JAR1 activity might have evolved independently in land plants.

462

463 *Expression of SmAOC1, SmOPR5, and SmJAR1*

464 Wounding and JA induce the expression of various genes involved in defense responses in
465 seed plants, i.e., genes encoding enzymes in JA biosynthesis. In *S. moellendorffii*, the expression
466 of *SmAOC1* and *SmOPR5* under wounding treatment was increased, respectively (Fig. 8). These
467 results were consistent with the transient increases in OPDA and JA in *S. moellendorffii* (Fig. 3).
468 Based on the *SmOPR5* expression level, the accumulation of *SmOPR5* appears to precede the
469 production of OPDA. Additionally, the late accumulation of JA-Ile coincided with the late
470 expression level of *SmJAR1* after wounding (Fig. 8). The expression profiles of *SmAOC1*,
471 *SmOPR5*, and *SmJAR1* support the accumulation patterns of OPDA, JA, and JA-Ile, probably due
472 to the role of jasmonates in regulating responses to environmental stress in S. *moellendorffii.*

473 The present study also demonstrated that JA induced the expression of *SmAOC1* and
474 *SmOPR5* in *S. moellendorffii*. JA treatment led to the accumulation of genes encoding enzymes in

475 the octadecanoid pathway, indicating positive feedback regulation of JA biosynthesis. The
476 expression of *SmAOC1* and *SmOPR5* was enhanced upon JA application, and these expression
477 patterns were similar to those observed under wounding treatment (Fig. 9). The JA-induced
478 expression of *SmAOC1* and *SmOPR5* allows us to infer the presence of positive feedback
479 regulation of JA biosynthesis in *S. moellendorffii*. In contrast to the up-regulation of *SmJAR1* by
480 wounding, JA inhibited *SmJAR1* expression at the transcriptional level (Fig. 9). Although the
481 detailed JA signaling pathway has not been elucidated in *S. moellendorffii*, the suppression of
482 *SmJAR1* expression by JA appears to function as negative feedback regulation of JA-Ile-mediated
483 signaling and/or an increase in JA signaling that is independent from JA-Ile. Wounding probably
484 activates various signaling pathways that are JA-dependent and JA-independent. In the case of
485 *SmJAR1* expression, integrated signaling caused by wounding might induce *SmJAR1* expression
486 against stresses.
487
488 *OPDA, JA, and JA-Ile inhibit the growth of S. moellendorffii*
489 *P. patens* and *M. polymorpha* cannot produce JA; instead, OPDA inhibits their growth, and
490 JA does not induce any significant physiological responses (Stumpe et al. 2010, Yamamoto et al.
491 2015). However, *P. patens* responds to methyl jasmonate, which has not been detected in *P.*
492 *patens,* by reducing its colony size (Ponce de León et al. 2012). Many studies have reported the
493 growth inhibitory activity of JA in seed plants. OPDA, JA, and JA-Ile treatment retarded the
494 growth of *S. moellendorffii* in a manner similar to those of seed plants (Fig. 10, Supplementary
495 Fig. 18). This report is the first evidence that OPDA, JA and JA-Ile inhibit the growth of non-
496 seed vascular plants. The growth inhibitory activity of JA and JA-Ile is probably a characteristic
497 physiological response that is conserved in vascular plants. During plant evolution, JA

biosynthesis and signaling in vascular plants might have developed due to the need to adapt to life on land and/or to organize more complicated physiological processes.

It has recently been reported that the genes encoding proteins related to JA signaling perception, such as COI1 and JAZ, are present in bryophytes and lycophytes (Wang et al. 2015). The JA responsiveness of *S. moellendorffii* shown in this study indicates that JA might function through a signal transduction mechanism similar to that observed in seed plants: the COI1-JAZ system. Given that JA does not have any significant effect in bryophytes, vascular plants are suggested to have developed the COI1-JAZ system, which is suitable for JA signaling. Investigating the functional difference in the COI1-JAZ system between bryophytes and lycophytes is important for understanding the functional evolution of JA signal transduction in plants. *S. moellendorffii* will be a key plant for understanding the function of JA in vascular plants.

In conclusion, we provide the first evidence of the presence of OPDA, JA, and JA-Ile in the model lycophyte *S. moellendorffii*, which is taxonomically positioned between bryophytes and euphyllophytes. Moreover, active homologous enzymes involved in the octadecanoid pathway, including an AOS, an AOC, an OPR3-like enzyme, and a JAR1, were also identified in this plant. The application of exogenous OPDA, JA, and JA-Ile significantly inhibited the growth of *S. moellendorffii.* Thus, OPDA, JA, and JA-Ile are probably important signaling molecules in stress responses and growth regulators in *S. moellendorffii.*

Materials and Methods

Plant material

520 *S. moellendorffii* was grown at 25°C under white fluorescent light with a photoperiod of 14 h
521 light/10 h dark.
522
523 *Analysis of OPDA, JA, and JA-Ile*
524 The microphylls and stems of *S. moellendorffii* (ca. 500 mg) were harvested 10, 20, 30, 60 or
525 180 min after wounding with tweezers and were homogenized in liquid nitrogen, followed by
526 ethanol extraction for 24 h. UPLC-MS/MS analysis was performed according to Sato et al.
527 (2009) and Yamamoto et al. (2015).
528
529 *JA growth inhibitory activity assay in S. moellendorffii*
530 *S. moellendorffii* bulbils (Supplementary Fig. S17) were sprinkled onto a Jiffy-7 pellet
531 (Sakata Seed Corporation, Japan). The bulbils were grown at 25°C under white fluorescent light
532 with a photoperiod of 14 h light/10 h dark. After germination and one week of growth, the plants
533 were treated with OPDA, JA, or JA-Ile at concentrations of 25 μM, 50 μM, and 100 μM every
534 other day for four weeks. The shoot growth of the plants was evaluated by morphometric analysis.
535
536 *Bioinformatics analysis*
537 All of the putative genes in *S. moellendorffii* were screened in the Phytozome v 11.0 database
538 (https://phytozome.jgi.doe.gov/pz/portal.html) using the *Arabidopsis* amino acid sequence as a
539 query (Supplementary Table S1). Multiple sequence analysis was performed using Clustal
540 Omega and viewed in the GeneDoc software program. A phylogenetic tree was generated using
541 Mega version 5.2 (Neighbor-joining method). Bootstrap analysis was performed by resampling
542 the datasets 1,000 times. The sub-cellular localization of *SmAOC1* was predicted using ChloroP v

543 1.1 (http://www.cbs.dtu.dk/services/ChloroP/) and TargetP (http://www.cbs.dtu.dk/services/
544 TargetP/). The theoretical pI and molecular weight were analyzed using the Compute pI/Mw tool
545 (http://web.expasy.org/compute_pi/).
546
547 *Molecular cloning of SmAOS2, SmAOC1, SmOPR1, SmOPR5, and SmJAR1-1*
548 The *SmAOS2*, *SmAOC1, SmOPR1, SmOPR5,* and *SmJAR1* genes were cloned according to a
549 conventional method. The details are described in the Supplemental Information.
550
551 *Synthesis of recombinant SmAOS2, SmAOC1, SmOPR1 and SmOPR5*
552 Recombinant SmAOS2, SmAOC1, SmOPR1 and SmOPR5 were produced according to a
553 conventional method. The details are described in the Supplemental Information.
554
555 *Enzyme assay of SmAOS2*
556 To measure AOS activity, SmAOS2 was reacted with 13(*S*)-HPOT according to Bandara et al.
557 (2009) with some modifications. Five milligrams of recombinant SmAOS2 was reacted with 6 μg
558 of 13(*S*)-HPOT as a substrate in a total volume of 0.1 ml of 50 mM phosphate buffer (pH 7.0).
559 The reaction mixture was incubated at 25°C for 1 h. To terminate the enzymatic reaction, the
560 mixture was treated with 1 M HCl until it reached pH 3. To convert *cis*-OPDA to *trans*-OPDA,
561 the reaction mixture was subjected to alkaline treatment by stirring with 1 ml of 1 M NaOH for
562 30 min. After acidification, the resulting solution was extracted three times with an identical
563 volume of ethyl acetate, evaporated, and methylated using ethereal diazomethane. After
564 incubation for 30 min on ice, the reaction was terminated with the addition of 1 or 2 drops of
565 acetic acid until the color changed from yellow to colorless. The methylated residue was

566 dissolved in 100 μl of $CHCl_3$ for chiral GC-MS analysis (1200 L GC-MS/MS system, Varian,
567 USA) equipped with a β–DEX fused silica capillary column (0.25 mm × 30 m × 0.25 μm,
568 Supelco, USA). Helium was used as the carrier gas at a constant flow rate of 1.0 ml/min. The ion
569 source and vaporizing chamber were heated to 200°C and 220°C, respectively, and the ionization
570 voltage was 70 eV. The column was initially heated to 50°C and held isothermally for 1 min, and
571 then the temperature was subsequently increased at a rate of 10°C/min to a final temperature of
572 190°C, which was held for 80 min.
573
574 *Enzyme assay of SmAOC1 activity*
575 The enzymatic reaction was performed in a mixture of 5 μg of 13-HPOT and 5 μg of
576 PpAOS1 in 1 ml of 10 mM sodium phosphate buffer (pH 7.8) with or without 10 μg of SmAOC1.
577 The reaction mixture was incubated at 25°C for 1 h. The products of the SmAOC1 reaction were
578 analyzed according to the method of OPDA analysis described in the previous section.
579
580 *Enzyme assays for OPR activity*
581 The enzymatic reaction was performed according to the method of Schaller et al. (1998) with
582 some modifications. Five micrograms of affinity-purified recombinant SmOPR1 or SmOPR5 was
583 incubated in 50 mM potassium phosphate buffer (pH 7.4) containing 7.5 μg of (±)-*cis*-OPDA as a
584 substrate and 1.0 mM NADPH in a total volume of 0.1 ml for 1 h at 25°C. At the end of the
585 incubation, (±)-*cis*-OPDA and (±)-*cis*-OPC-8:0 were converted to methylated *trans*-isomers
586 according to the method described above. OPC-8:0 was evaluated by chiral GC-MS analysis
587 (same conditions as the enzymatic analysis for SmAOC1).
588

589 *Subcellular localization of SmAOC1*

590 Subcellular localization of SmAOC1 was analyzed according to the method of Yamamoto et
591 al. (2015). The details are described in the Supplemental Information.

592

593 *Enzyme assays for JAR1 activity*

594 SmJAR1 activity was assayed according to Wakuta et al. (2011) with some modifications. *E.*
595 *coli* BL21 (DE3) cells carrying pET23a-SmJAR1 were cultured overnight in 5 ml of LB medium
596 supplemented with 100 μg/ml ampicillin, at 37°C. A portion of the culture was inoculated into 2
597 ml of fresh selective LB medium, incubated until the OD_{600} reached 0.2, and treated with 1 mM
598 IPTG. The culture was incubated at 37°C for 5 h to induce protein production. Subsequently, 0.2
599 mM JA was added to the culture. The incubation was continued at 37°C for 3 h with shaking. JA-
600 Ile in the culture was analyzed using the UPLC-MS/MS system as previously described (Sato et
601 al. 2009).

602

603 *Quantitative RT-PCR for SmAOC1, SmOPR5, and SmJAR in S. moellendorffii exposed to*
604 *wounding stress and JA treatments*

605 The coding sequences (CDSs) for *SmAOC1*, *SmOPR5*, and *SmJAR1* were used to design
606 specific primers for quantitative RT-PCR (qRT-PCR). The primers used to amplify these genes
607 are listed in Supplementary Table S1. Total RNA of *S. moellendorffii* was extracted 0, 10, 20, 30,
608 60, and 180 min after wounding or 50 μM JA treatment. The first-strand cDNA was used as a
609 template. In the present study, KOD SYBR qPCR Mix (Toyobo, Japan) was used according to
610 the manufacturer's protocol. Each reaction mixture contained 12.5 μl of KOD SYBR® qPCR Mix,
611 1 μl of each primer (10 mM), 1 μl of cDNA, and 9.5 μl of MilliQ water qRT-PCR was performed

612 on a Thermal Cycler Dice Real Time system (Takara TP800, Japan). The qRT-PCR conditions
613 were as follows: pre-incubation at 95°C for 30 s, followed by 40 cycles of 95°C for 5 s and 60°C
614 for 30 s. The specificity of each PCR amplicon was assessed with a dissociation curve (95°C for
615 15 s, 60°C for 30 s, and 95°C at 15 s). Each target gene was calculated and expressed as fold
616 regulation in comparison to the housekeeping genes actin (XM_002976966) for the wounding
617 treatment and ubiquitin EST (DN839032, Kirkbride et al. 2013) for the JA treatment.
618
619 **Funding information**

866

867 Fig. 1. The biosynthesis of JA and JA-Ile.

868

869 Fig. 2. UPLC-MS/MS analysis of OPDA, JA, and JA-Ile in *S. moellendorffii*. (A−C) MRM mode
870 analysis of a specific daughter peak at *m/z* 164.99 that was derived from the peak at *m/z* 291.37
871 $[M-H]^-$. (D−F) MRM mode analysis of a specific daughter peak at *m/z* 58.71 that was derived
872 from the peak at *m/z* 209.09 $[M-H]^-$. (G−I) MRM mode analysis of a specific daughter peak at
873 *m/z* 129.68 that was derived from the peak at *m/z* 322.03 $[M-H]^-$. (A, D, G) Standard. (B, E, H) *S.*
874 *moellendorffii* extract. (C, F, I) Co-injection of the standard and *S. moellendorffii* extract.

875

876 Fig. 3. Accumulation of OPDA, JA, and OPDA in *S. moellendorffii* after wounding. *S.*
877 *moellendorffii* was subjected to mechanical wounding and then collected at the indicated time
878 after wounding. The concentrations of OPDA, JA, and JA-Ile were analyzed by UPLC-MS/MS.
879 The data are presented as the mean ± SD (n = 3). The asterisks represent a significant difference
880 between the treated and control plants (Student's t-test, $*p < 0.05$, $**p < 0.01$).

881

882 Fig.4. Chiral GC-MS analysis of the OPDA methyl ester. Recombinant SmAOS2 was reacted
883 with the substrate 13(*S*)-HPOT, directly treated with alkaline solution and then methylated by
884 ethereal diazomethane. The methylated OPDA was analyzed by GC-MS using a chiral capillary
885 column. The data are presented as the total ion current chromatogram. The former and latter
886 peaks represent the *trans*-(+)- and (−)-OPDA methyl esters, respectively (Laudert et al. 1997).

887

888 Fig. 5. Chiral GC-MS analysis of the OPDA methyl ester. Recombinant SmAOC1 was reacted
889 with the substrate 13-HPOT and an allene oxide synthase (PpAOS1), directly treated with
890 alkaline solution and then methylated by ethereal diazomethane. The methylated OPDA was
891 analyzed by GC-MS using a chiral capillary column. The molecular ion peak of the OPDA
892 methyl ester at *m/z* 306 was monitored. The former and latter peaks represent the *trans*-(+)- and
893 (−)-OPDA methyl ester, respectively (Laudert et al. 1997). (A) Racemic OPDA standard. (B)
894 Product of the SmAOC1 enzymatic reaction.
895
896 Fig. 6. Chiral GC-MS analysis of the reaction products catalyzed by SmOPR1 and SmOPR5.
897 Recombinant SmOPR1 and SmOPR5 were each reacted with racemic OPDA, directly treated
898 with alkaline solution and then methylated by ethereal diazomethane. The methylated reaction
899 products were analyzed by GC-MS using a chiral capillary column. The data are presented as the
900 total ion current chromatogram. Peaks 1 to 4 represent *trans*-isomers of (+)-OPC-8:0 (natural
901 type), (−)-OPC-8:0, (+)-OPDA (natural type) and (−)-OPDA, respectively, that were derived
902 from *cis*-isomers of these compounds.
903
904 Fig. 7. UPLC-MS/MS analysis of JA-Ile in *E. coli* overexpressing SmJAR1. MRM mode analysis
905 of a specific daughter peak of JA-Ile-d_6 at *m/z* 129.68 that was derived from the peak at m/z
906 328.03 $[M-H]^-$ and of the peak at *m/z* 129.68 that was derived from the peak of JA-Ile at *m/z*
907 322.03 $[M-H]^-$. (A) Internal standard JA-Ile-d_6. (B) Culture supernatant of *E. coli*
908 overexpressing SmJAR1. (C) Culture supernatant of *E. coli* containing pET23a as a control. *The
909 value of 100% is equal to 9×10^5 counts, which was converted by the algorithm in Mass Lynx
910 software (Waters Corporation, Milford, MA, USA).

911

912 Fig. 8. Quantitative RT-PCR analysis of *SmAOC1*, *SmOPR5*, and *SmJAR1* in wounded *S.*
913 *moellendorffii.* Plants were subjected to mechanical wounding and then collected at the indicated
914 times after wounding. To evaluate the transcript levels of *SmAOC1*, *SmOPR5*, and *SmJAR1*,
915 qRT-PCR was performed using RNA isolated from control and wounded plants. The data are
916 presented as the mean ± SD (n = 3). The asterisks represent a significant difference between the
917 treated and control plants (Student's t-test, $*p < 0.05$; $**p < 0.01$).

918

919 Fig. 9. Quantitative RT-PCR analysis of *SmAOC1*, *SmOPR5*, and *SmJAR1* in *S. moellendorffii*
920 treated with JA. Plants were treated with 50 μM JA and then collected at the indicated times after
921 JA treatment. To evaluate the transcript levels of *SmAOC1*, *SmOPR5*, and *SmJAR1*, qRT-PCR
922 was performed using RNA isolated from control and JA-treated plants. The data are presented as
923 the mean ± SD (n = 3). The asterisks represent a significant difference between the treated and
924 control plants (Student's t-test, $*p < 0.05$; $**p < 0.01$; $***p < 0.001$).

925

926 Fig. 10. Growth inhibitory activities of OPDA, JA, and JA-Ile in *S. moellendorffii*. *S.*
927 *moellendorffii* was treated with OPDA, JA, and JA-Ile for four weeks, and then the shoots were
928 measured. The data are presented as the mean ± SD (n = 5). The asterisks represent a significant
929 difference between the treated and control plants (Student's t-test, $**p < 0.01$; $***p < 0.001$).
