　過活動膀胱（Overactive Bladder, OAB）は 2002 年に国際禁制学会が定義した疾患である。[1]過活動膀胱では、主に蓄尿時に不随意的に膀胱が収縮する排尿筋過活動により正常な蓄尿が困難になり、急な尿意をもよおし、我慢できないほどの尿意切迫感、さらに頻尿（昼間頻尿、夜間頻尿）や切迫性尿失禁（尿漏れ）などの諸症状が認められる。これら過活動膀胱の症状は患者にとって高いストレスとなり、そして生活の質を大きく下げる。[2]

　人口をベースとした 5 か国（カナダ、ドイツ、イタリア、スウェーデン、イギリス）における推定によると、18 歳以上の約 12%が過活動膀胱の症状を有していると考えられている。[3]また、男性と女性の割合に大きな差は無く、年齢の上昇と共に患者が増える傾向がある。また、日本における日本排尿機能学会が行った調査によると 40 歳以上の過活動膀胱の有病率は 12.4%であり、有病者は 810 万人と推定されている。[4]

　現在、過活動膀胱の治療の第一選択薬である抗コリン薬（ムスカリン受容体アンタゴニスト）は、排尿回数、尿意切迫感を改善させるものの、口渇、便秘、視力障害、尿閉などの副作用が報告されている。[5]それらの副作用はムスカリン受容体アンタゴニストの作用メカニズムに関連がある。[5b]すなわち、標的分子であるムスカリン受容体は膀胱の他に唾液腺にも発現しており、そのアンタゴニストは口渇を引き起こす。また、抗コリン薬は膀胱収縮を抑える働きをするため、残尿も生じやすい。近年、膀胱選択性を高めた抗コリン薬も開発されているが、副作用、特に口渇を完全に回避するまでには至っていない。

　近年の調査によると、抗コリン薬を 12 か月間継続投与できた過活動膀胱の患者は 35%以下であり、抗コリン薬の副作用は過活動膀胱患者の長期間服薬が困難であることを示唆しており、その結果として治療満足度の低下につながっている。[6]

　上記治療満足度を向上させるために、過活動膀胱治療薬の新規標的分子として、アドレナリン受容体（adrenergic receptor, AR）の一つであるβ_3-AR が注目されている。[7] アドレナリン受容体はα_1-AR、α_2-AR、β-AR の 3 つのサブファミリーに分類されており、その β-AR はβ_1、β_2、β_3 の 3 つのサブタイプが知られている。[8]アドレナリン受容体の生体内リガンドはアドレナリン、ノルアドレナリンである。[8]

　G タンパク共役型受容体であるβ_3-AR は、1980 年代にヒトゲノム解析により発見されたβ-AR サブタイプの 1 つである。[8-9]β_3-AR は脂肪細胞の分解や熱発生、さらに胆嚢、胃、小腸、前立腺、結腸、膀胱の弛緩に関わっていることが知られている。[10]特に、ヒト膀胱組織におけるβ-AR の mRNA を解析した結果、97%がβ_3-AR であることが報告されており[11]、ヒトの膀胱弛緩においてβ-AR のサブタイプのうち、β_3-AR が最も重要な機能を持っていることが示唆されている[12]。さらに、β_3-AR アゴニストはラットにおける蓄尿を向上させた[13]ことから、β_3-AR アゴニストは抗コリン薬に見られる副作用を示さない新規メカニズムの過活動膀胱治療薬として非常に期待されている[14]。

　過活動膀胱の治療薬として臨床試験が実施されたβ_3-AR アゴニストは 1 (ミラベグロン、mirabegron、YM-178)[15]、2 (ソラベグロン、solabegron、GW427353)[16]、3 (リトベグロン、ritobegron、KUC-7483)[17]、4 (ビベグロン、vibegron、MK-4618)[14b]が知られている（Figure 1）。ミラベグロン（1）は過活動膀胱の治療薬として承認されており[18]、β_3-AR アゴニストという新規メカニズムであるため、抗コリン薬と比較して口渇等の副作用が少ないことが特徴である[7]。

mirabegron (**1**)

solabegron (**2**)

ritobegron (**3**)

vibegron (**4**)
Figure 1. Chemical structures of **1**, **2**, **3**, and **4**.

しかしながら、ミラベグロンは血圧上昇や心拍数上昇など心血管系に対する副作用を引き起こすことが知られている。[7]その原因は特定されていないものの、ミラベグロンの心拍数上昇作用に関しては β_1-AR*に対するアゴニスト活性が原因の一つとして考えられる。[20]さらに、ミラベグロンは CYP2D6 に対する阻害作用があるため、CYP2D6 で代謝される医薬との薬物間相互作用が懸念される。[21]

上述の通り、現在上市されているミラベグロンにはいくつか懸念点がある。そのミラベグロンよりも優れた治療薬を目指し、β_3-AR に対する高い選択性を持ち、血圧上昇を含む心血管系の副作用を軽減した新規な化合物を創出することで、ベストインクラスの過活動膀胱治療薬になると考え、本研究に着手した。

第1章　新規なインダゾール骨格を有するβ3-AR アゴニスト化合物 11 の創出

第1節　ヒット化合物取得の戦略

　AR の生体内リガンドであるアドレナリン、β-AR 非選択的アゴニストであるイソプロテレノール、代表的なβ3-AR アゴニストであるミラベグロン並びにソラベグロンに共通する部分構造はアリールエタノールアミンであり、β3-AR アゴニスト活性を示すにはアリールエタノールアミンが必須構造であると考えた（Figure 2、赤色部分）。一方、イソプロテレノールとβ3-AR アゴニストの構造上の違いは、アリールエタノールアミンの右側にアミノチアゾールやビアリールカルボン酸などを有することである（Figure 2、点線内）。従って、β3-AR アゴニスト活性を有する新規なヒット化合物の取得を目的として、アリールエタノールアミンの右側にβ3-AR と水素結合が期待できる種々の 2 環性ヘテロ環[*]をエーテルリンカーで結合したライブラリーに対し、β3-AR アゴニスト活性評価を実施した（Figure 2、中段）。その評価方法はβ3-AR を発現させた Chinese Hamster Ovary （CHO） 細胞を用いて、細胞内の cAMP を定量した。その結果、アリールエタノールアミンの右側にインダゾール骨格を有する化合物 5 をヒット化合物として見出した（Figure 2、下段）。Table 1 に化合物 5 の AR アゴニスト活性 EC_{50}[†]とその内在活性（intrinsic activity, IA）[‡]示す。化合物 5 は強いβ3-AR アゴニスト活性（EC_{50} = 21 nM）、並びにβ1-AR とβ2-AR[§]に対して高いβ3-AR 選択性（β1/β3、β2/β3 >476-fold）を有していた。化合物 5 は文献等で報告されている他のヒット化合物[22]（Figure 3）と比較し、β1 とβ2-AR アゴニスト活性が非常に弱く、β3-AR に対して極めて高選択的な特徴を有しているため、さらに詳細な薬理プロファイルを検討した。

　β1-AR とβ2-AR に無効な高選択的β3-AR アゴニストが血圧心拍に与える影響を確認するために、麻酔下のラットに対して化合物 5 を静脈内投与した。その結果を Table 2 に示す。化合物 5 投与後、一過的な二相性の平均血圧（mean blood pressure, MBP）の変化（明らかな上昇と若干の低下）が観測された。その変化は投与後 5 分以内で起き、その後ベースラインに戻った。MBP の最大上昇率は 24.2%、最大低下率は 8.5%であった。また、血圧（heart rate, HR）は投与後 1-5 分の間で 7.9%上昇した。なぜ、高選択的なβ3-AR アゴニストである化合物 5 が血圧上昇を引き起こしたのかを考察するために、β-AR のサブファミリーであるα1-AR[**]とα2-AR[††]のアゴニスト活性を評価した。その結果を Table 1 に示す。化合物 5 はα1A-AR に対して強いアゴニスト活性（EC_{50} = 219 nM）を有することが分かった。α1-AR は広く全身に分布しており、特に心血管系組織、平滑筋、脳に発現している。[23]また、α1-AR アゴニストは末梢の血管収縮を介して血圧を上昇させることが知られている。[24]さらに、化合物 5 の血圧上昇はα1A-AR アンタゴニストであるシロドシン[25]を事前投与することにより、完全に抑制された。ゆえに、化合物 5 の血圧上昇はα1-AR アゴニスト活性に由来すると示唆された。したがって、筆者はα1A-AR アゴニスト活性を減弱させたβ3-AR に高選択的な化合物創出を目指し、ヒット化合物 5 の構造をベースに化合物最適化研究を実施した。

第2節　α_{1A}-AR に対する選択性向上のための化合物設計方針

　上述の通り、化合物 **5** はラットにおいて血圧上昇を示したことから、化合物 **5** のα-AR に対する選択性評価に加え、化合物 **5** のラットによる代謝物が血圧上昇を引き起こす可能性を考慮し、肝ミクロソームによる代謝安定性評価と代謝物構造解析も行った。化合物 **5** はヒトミクロソームに対して *in vitro* 代謝安定性（CL$_{int,u}$)[*]は良好であったが、ラットミクロソームに対して代謝安定性は低かった（human CL$_{int,u}$ < 10 mL/min/kg、rat CL$_{int,u}$ = 103 mL/min/kg）。さらに、ラットミクロソームによる代謝物の構造解析を行った結果、ラットにおける主代謝物としてインダゾール 3 位のメチル基が水酸化された化合物 **6** を同定した（Figure 4）。その水酸化体 **6** はβ_3-AR とα_{1A}-AR のアゴニスト活性を示し（β_3-AR EC$_{50}$ = 111 nM、α_{1A}-AR EC$_{50}$ = 33 nM）、特に、α_{1A}-AR アゴニスト活性は化合物 **5** よりも強かった。一方、化合物 **5** はヒトミクロソームの代謝安定性が良好なため、ヒトの代謝において水酸化体 **6** はほとんど生成しないと考えられる。

　ラット主代謝物解析から同定された水酸化体 **6** のβ_3-AR とα_{1A}-AR のアゴニスト活性評価より、化合物 **5** のインダゾール 3 位のメチル基をヒドロキシメチル基に変換することは大きくα_{1A}-AR アゴニスト活性を変化させるという構造最適化のきっかけをつかむことができた。すなわち、インダゾール 3 位の置換

---

[*] 数字が大きいほど代謝に対して不安定であることを示している

基はα_{1A}-AR アゴニスト活性に重要な変化を及ぼすと予想した。そこで、筆者はインダゾール 3 位の置換基変換を行うことで、α_{1A}-AR アゴニスト活性に対して選択性を向上させたβ_3-AR アゴニストを創出できると考え、合成を行った。

β_3-AR EC$_{50}$ = 21 nM β_3-AR EC$_{50}$ = 111 nM
α_{1A}-AR EC$_{50}$ = 219 nM α_{1A}-AR EC$_{50}$ = 33 nM

第3節　インダゾール 3 位の変換による構造－β_3-AR 並びにα_{1A}-AR アゴニスト活性相関

（1）構造－β_3-AR アゴニスト活性相関

　Table 3 にインダゾール 3 位を変換した化合物のβ_3-AR アゴニスト活性を示す。メチル基 **5** をメトキシ基 **7** に変換した結果、β_3-AR アゴニスト活性は向上しなかった（**5**, EC$_{50}$ = 21 nM vs. **7**, EC$_{50}$ = 40 nM）。一方、メチル基 **5** をエトキシ基 **8** に変換した結果、活性が減弱した（**5**, EC$_{50}$ = 21 nM vs. **8**, EC$_{50}$ = 71 nM）。また、メチル基 **5** をクロロ基 **9**、エチル基 **10**、イソプロピル基 **11**、シクロプロピル基 **13** に変換した結果、活性にほとんど変化はなかった（**5**, EC$_{50}$ = 21 nM vs. **9**, EC$_{50}$ = 43 nM; **10**, EC$_{50}$ = 14 nM; **11**, EC$_{50}$ = 13 nM; **13**, EC$_{50}$ = 17 nM）。しかし、メチル基 **5** を t‐ブチル基 **12** もしくはフェニル基 **16** に変換した結果、活性が大きく減弱した（**5**, EC$_{50}$ = 21 nM vs. **12**, EC$_{50}$ = 338 nM, **16**, EC$_{50}$ = >10000 nM）。シクロブチル基 **14**、トリフルオロメチル基 **15** はメチル基 **5** よりも活性がやや減弱した（**14**, EC$_{50}$ = 66 nM, **15**, EC$_{50}$ = 64 nM vs. **5**, EC$_{50}$ = 21 nM）。以上をまとめると、β_3-AR アゴニスト活性の強さの順は **5, 7, 9, 10, 11, 13** > **8, 14, 15** > **12** > **16** であった。

　イソプロピル基 **11** よりも大きい置換基である t‐ブチル基 **12** やフェニル基 **16** はβ_3-AR アゴニスト活性が減弱することから、イソプロピル基以下のサイズがβ_3-AR との結合に適していると考えられる。その原因は置換基がイソプロピル基よりも大きい場合、β_3-AR のアミノ酸残基と反発することが推定される。

（2）構造－α_{1A}-AR アゴニスト活性相関

　Table 3 にインダゾール 3 位を変換した化合物のα_{1A}-AR アゴニスト活性を示す。まず、メトキシ体 **7** あるいはエトキシ体 **8** は、α_{1A}-AR アゴニスト活性に変化は無かった（**5**, EC_{50} = 219 nM vs. **7**, EC_{50} = 252 nM, **8**, EC_{50} = 277 nM）。また、クロロ体 **9** はメチル体 **5** よりもα_{1A}-AR アゴニスト活性が向上した（**9**, EC_{50} = 61 nM vs. **5**, EC_{50} = 219 nM）。一方、エチル体 **10**、シクロプロピル体 **13**、トリフルオロメチル体 **15** へと変換した結果、大きくα_{1A}-AR アゴニスト活性が減弱した（**5**, EC_{50} = 219 nM vs. **10**, EC_{50} = 857 nM; **13**, EC_{50} = 1548 nM; **15**, EC_{50} = 812 nM）。さらに、イソプロピル体 **11**、 t－ブチル体 **12**、シクロブチル体 **14** あるいはフェニル体 **16** は、α_{1A}-AR アゴニスト活性を示さなかった。以上をまとめると、α_{1A}-AR アゴニスト活性の強さの順は **9** > **5, 7, 8** > **10, 13, 15** >> **11, 12, 14, 16** であった。

　メトキシ体 **7** 並びに Figure 4 のヒドロキシメチル体 **6** が強いα_{1A}-AR アゴニスト活性（α_{1A}-AR EC_{50} = 33 nM）を示したことからインダゾール 3 位ヒドロキシメチル基やメトキシ基はα_{1A}-AR のアミノ酸残基と水素結合等の相互作用をしている可能性が考えられる。一方、イソプロピル体 **11** のような分岐アルキル基は嵩高く、疎水性が高いために上記水素結合を形成することができず、α_{1A}-AR アゴニスト活性を示さないことが推測される。

（3）α_{1A}/β_3 選択性の構造相関

　β_3-AR アゴニスト活性とα_{1A}-AR アゴニスト活性を基に、α_{1A}-AR に対してβ_3-AR の選択性の順は **11** > **14** > **13** > **10** > **12** > **15** > **5** > **7** > **8** > **9** であった。ゆえに、β_3-AR アゴニスト活性の強さとα_{1A}-AR に対する選択性から化合物 **10**、化合物 **11** 並びに化合物 **13** を選択し、更なる薬理評価を実施した。

（4）β_1-AR とβ_2-AR のアゴニスト活性

　Table 4 にβ_3、β_2、 β_1、並びにα_{1A}-AR に対するアゴニスト活性を示す。化合物 **10**、化合物 **11**、並びに化合物 **13** はβ_1-AR とβ_2-AR に対してアゴニスト活性を示さなかった（β_1-AR EC_{50} = >10000 nM; β_2-AR EC_{50} = >10000 nM）。したがって、これら 3 化合物はβ_3-AR 高選択的アゴニストであることが示唆された。

第4節　ラットの心血管系に与える影響

　上述の通り、化合物 **10**、化合物 **11** 並びに化合物 **13** はβ₃-AR 高選択的であることが示されたので、ラットを用いて心血管系に与える影響を評価し、ヒット化合物 **5** 並びにミラベグロン（**1**）と比較した。Table 5 に結果を示すように、インダゾール 3 位が最適化された 3 化合物はすべて MBP の上昇を引き起こさなかった。一方、ヒット化合物 **5** は大きく MBP の上昇（24.2%）を引き起こした。同様の評価にて、ミラベグロン（**1**）は MBP の大きな低下（38.3%）を引き起こした。また、化合物 **11** は HR に関して影響を与えなかった。一方、ミラベグロン（**1**）は HR の上昇（10.0%）を引き起こした。MBP と HR の結果より、化合物 **10**、化合物 **11** 並びに化合物 **13** はミラベグロン（**1**）並びにヒット化合物 **5** と比較し、MBP や HR に与える影響は少なく、その要因はβ₃-AR に高選択的であることが示唆された。

第5節　化合物 **11** の排尿筋弛緩作用に関して

　次に、化合物 **11** の膀胱平滑筋に対する弛緩作用を評価した。これまでにラットを用いた膀胱平滑筋に対する評価法が知られている[15]が、化合物 **11** はヒトとラットでβ₃-AR に対する活性に種差があり、ラットのβ₃-AR アゴニスト活性が弱かった（EC₅₀ = 535 nM, IA = 95%）。種々の動物に対するβ₃-AR アゴニスト活性を評価した結果、化合物 **11** はマーモセットに対して強いβ₃-AR アゴニスト活性を有することが分かった（EC₅₀ = 15 nM, IA = 75%）。ゆえに、化合物 **11** はマーモセットを用いて膀胱平滑筋に対する弛緩作用を確認した。本評価では、マーモセットの膀胱を摘出し、事前に塩化カリウムを用いて排尿筋を収縮させた後、化合物を添加して膀胱平滑筋の弛緩を測定した。Figure 5 に示すように、化合物 **11** は用量依存的に弛緩作用を示し、その最大弛緩率は陽性対象の非選択的β-AR アゴニストであるイソプロテレノールと同等であった。この結果からマーモセットの膀胱弛緩は高選択的β₃-AR アゴニスト **11** の作用で十分に引き起こすことができると考えられ、その弛緩作用は蓄尿時の膀胱用量の増大につながると推定される。
Figure 5. Relaxation of marmoset urinary bladder smooth muscle by **11**. Each point represents the mean ± SD (n = 3). The marmoset urinary bladder was cut by a midline incision and 6 muscle strips of the bladder body were prepared. The strips were pre-contracted with 40 mmol/L KCl, and, after the tension had stabilized, test compounds were cumulatively added. When the relaxation response at the maximum concentration of the test compound was completed, papaverine was added at a final concentration of 10^{-4} mol/L, and the maximum relaxation response of each strip was determined. See Experimental Section for further details.

第6節　インダゾール誘導体 **5**〜**16** の合成
（1）ターゲット化合物 **5**〜**16** の合成ルート
インダゾール誘導体である化合物 **5**〜**16** の合成に関して Scheme 1 に示す。アルコール中間体 **17** とインダゾール中間体 **18**〜**28** に対して光延反応を用いてエーテル結合を形成し、続いて塩酸を用いて保護基を除去することにより化合物 **5** 並びに化合物 **7**〜**16** を合成した。同様の方法にて、アルコール中間体 **17** とインダゾールエステル中間体 **29** を光延反応にて結合させることで **30** を得た。**30** のエチルエステルを加水分解により、カルボン酸へと誘導後、そのカルボン酸をボラン－ＴＨＦ錯体を用いてアルコールへと還元、続く塩酸による脱保護にて、化合物 **6** を得た。

第7節　第1章まとめ

　アリールエタノールアミンライブラリーから見出したヒット化合物 **5** のインダゾール 3 位を変換することにより、β$_3$-AR に高選択的な化合物 **11** を見出した。化合物 **11** はマーモセットに対して用量依存的に排尿筋弛緩作用を示した。さらに、化合物 **11** はミラベグロン（**1**）と比較し、ラットを用いた血圧心拍の評価において影響を与えなかった。したがって、化合物 **11** はβ$_3$-AR 高選択的であり、心血管系に対する副作用が少ない特徴を有していることが示唆された。

第2章　スルホンアミド変換による薬物動態プロファイルの最適化

第1節　化合物 **11** 並びにその類縁体の薬物動態プロファイル

　過活動膀胱の治療薬は患者が容易に服用できる経口剤が望ましいため、第 1 章で述べた代表的な 4 化合物が経口投与可能かどうか薬物動態プロファイルの評価を実施した。*in vitro* 薬物動態の結果を Table 6 に示す。第 1 章の第 2 節で述べたように、化合物 **5** は *in vitro* ヒトミクロソーム代謝安定性（CL$_{int,u}$）[*]が良好であったが、化合物 **11** 並びに化合物 **14** は化合物 **5** と比較し、ヒトミクロソーム並びにラットミクロソームに対する代謝安定性が低かった。また、*in vivo* の薬物動態プロファイル並びに膜透過性、水溶性のプロファイルを Table 7 に示す。化合物 **11** は *in vivo* の薬物動態プロファイル（C$_{max}$ and AUC）が化合物 **5** と比較して悪かった。一方、化合物 **11** は中程度の膜透過性、良好な水溶性を示したことから、化合物 **11** の低い C$_{max}$ と AUC は代謝安定性が低いことに由来すると示唆された。

　第 1 章で述べたように、インダゾールの 3 位の置換基がβ$_3$-AR 選択性に重要であり、β$_3$-AR に対する選択性の高い順番はイソプロピル体 **8** ＞シクロブチル体 **7** ＞エチル体 **6** ＞メチル体 **5** である。一方、ヒト代謝安定性が高い順番はメチル体 **5** ＞エチル体 **6** ＞イソプロピル体 **8** ＞シクロブチル体 **7** であった。ゆえに、β$_3$-AR 選択性が高い化合物ほど、代謝的に不安定であり、経口剤として適さないことが示唆された。すなわち、経口投与可能な過活動膀胱治療薬に仕上げるには、化合物 **11** の代謝的不安定性を改善する必要がある。したがって、この課題を克服するためにさらなる化合物最適化を実施した。

第2節　高いβ₃-AR 選択性とヒト代謝安定性を両立する最適化の方針

　Altenbach らは、スルホンアミドを持つα₁A-AR アゴニスト **54** の構造活性相関を報告している。[31]すなわち、Figure 6 に示すように、化合物 **54** のスルホンアミド基のアルキルが大きくなるにつれ、α₁A-AR アゴニスト活性が減弱し、さらに、芳香環を持つスルホンアミド基に変換すると、α₁A-AR アゴニスト活性が無くなったと述べている。一方、Sawa らは、アルキルスルホンアミド **55a** と芳香族スルホンアミド **55b** を比較し、**55a** よりも **55b** の方がβ₃-AR アゴニスト活性が強いことを報告している。[32]これら 2 つの文献報告を参考にして、筆者はα₁A/β₃-AR 選択性は低いが、ヒト代謝安定性が高い化合物 **5** のスルホンアミド基の置換基の大きさを変換するターゲット化合物 **56** を設計した。なお、第 1 章でインダゾールメチル体 **5** のラット代謝物解析から水酸化体 **6** を同定したが、化合物 **5** 自体のヒト代謝安定性は良好であることから、ターゲット化合物 **56** はヒト代謝安定性とα₁A/β₃-AR 選択性の両立が期待される。

第３節　スルホンアミド部分の変換による構造－β_3-AR 並びにα_{1A}-AR アゴニスト活性相関

（１）構造－β_3-AR アゴニスト活性相関

　Table 8 にスルホンアミド基を変換した化合物のβ_3-AR アゴニスト活性を示す。メチル基 **5** を *n*－プロピル基 **56a** に変換した結果、活性が若干向上した（**5**, EC_{50} = 21 nM vs. **56a**, EC_{50} = 6.5 nM）。しかし、イソプロピル基 **56b** への変換はメチル基 **5** と比較し、活性が低下した（**5**, EC_{50} = 21 nM vs. **56b**, EC_{50} = 70 nM）。次にシクロアルキル基へと変換した結果、シクロプロピル基 **56c** とシクロブチル基 **56d** はイソプロピル基 **56b** と比較して活性が向上した（**56b**, EC_{50} = 70 nM vs. **56c**, EC_{50} = 43 nM; **56d**, EC_{50} = 18 nM）。しかし、シクロペンチル基 **56e** はイソプロピル基 **56b** よりも大きく活性が低下した（**56b**, EC_{50} = 70 nM vs. **56e**, EC_{50} = 309 nM）。一方、フェニル基 **56f** への変換は EC_{50} = 3.9 nM を示し、アルキル基よりも活性が向上した。

以上をまとめると、β3-AR アゴニスト活性の強さの順は **56f > 56a > 56d, 5 > 56c > 56b > 56e** であった。

　スルホンアミドのアルキル基の変換にて n－プロピル基 **56a** とシクロブチル基 **56d** はイソプロピル基 **56c** やシクロペンチル基 **56e** と比較し、β3-AR アゴニスト活性が強いことから、n－プロピル基やシクロブチル基のサイズがβ3-AR との結合に良い効果を示していると考察した。一方、フェニル基 **56f** がアルキル基と比較して大幅に活性向上した結果はβ3-AR のアミノ酸残基と CH-π もしくはπ-π のような相互作用をしていると推定した。

（２）構造－α1A-AR アゴニスト活性相関

　Table 8 にスルホンアミド基を変換した化合物のα1A-AR アゴニスト活性を示す。n－プロピル体 **56a** はメチル体 **5** と比較し、α1A-AR アゴニスト活性に変化は無かった（**5**, EC_{50} = 219 nM vs. **56a**, EC_{50} = 163 nM）。一方、イソプロピル体 **56b** もしくはシクロプロピル体 **56c** は、メチル体 **5** と比較し、α1A-AR アゴニスト活性が減弱した（**5**, EC_{50} = 219 nM vs. **56b**, EC_{50} = 1757 nM; **56c**, EC_{50} = 1250 nM）。さらに、シクロブチル体 **56d**、シクロペンチル体 **56e** もしくはフェニル体 **56f** はα1A-AR アゴニスト活性を示さなかった（EC_{50} >10000 nM）。以上をまとめると、α1A-AR アゴニスト活性の強さの順は **5**, **56a** > **56c**, **56b** >> **56d**, **56e**, **56f** であった。

　n－プロピル体 **56a** はイソプロピル体 **56b** よりも 10 倍α1A-AR アゴニスト活性が強いので、直鎖のアルキル基はα1A-AR との結合に適していると考察した。また、シクロブチル基 **56d**、シクロペンチル基 **56e** もしくはフェニル基 **56f** は全くα1A-AR アゴニスト活性を示さなかったことから、嵩高い置換基はα1A-AR との結合に不利であると推定した。

（３）α1A/β3 選択性の構造相関

　β3-AR アゴニスト活性とα1A-AR アゴニスト活性を基に、α1A-AR に対してβ3-AR の選択性の順は **56f > 56d** >> **56a**, **56b**, **56c**, **56e** > **5** であった。ゆえに、α1A-AR に対するβ3-AR 選択性を考慮し、化合物 **56f** と化合物 **56d** を選択し、β1 とβ2-AR の選択性評価を実施した。

（４）β1-AR とβ2-AR のアゴニスト活性

　Table 9 に示すように、化合物 **56d** と化合物 **56f** はβ1 とβ2-AR に対してアゴニスト活性を示さなかった（EC_{50} >10000 nM）。ゆえに、化合物 **56d** と化合物 **56f** はβ3-AR に高選択的な化合物であることが示唆された。

第 4 節　化合物 **56d** と化合物 **56f** の薬物動態プロファイル

　Table 10 に *in vitro* 薬物動態プロファイル並びにラットに経口投与した際の *in vivo* 血漿中濃度を測定した結果を示す。化合物 **56d** は化合物 **11** と比較し、ヒトミクロソーム代謝安定性が向上した（**11**, hCL$_{int,u}$ = 193 mL/min/kg vs. **56d**, hCL$_{int,u}$ = 57 mL/min/kg）。一方、化合物 **56f** は化合物 **11** よりもヒトミクロソーム代謝安定性が低下した（**11**, hCL$_{int,u}$ = 193 mL/min/kg vs. **56f**, hCL$_{int,u}$ = 464 mL/min/kg）。ラットミクロソーム代謝安定性に関しても同様の傾向を示し、化合物 **56d** は化合物 **11** と比較して 4 倍優れていた（**11**, rCL$_{int,u}$ = 211 mL/min/kg vs. **56d**, rCL$_{int,u}$ = 52 mL/min/kg）。また、化合物 **56d** と化合物 **56f** は中程度の膜透過性を示し、pH 1.2 と pH 6.8 の溶液に対する溶解度は優れていた。さらに、代謝安定性が向上した化合物 **56d** は化合物 **11** と比較してラットにおける経口吸収性（C$_{max}$、AUC 並びに半減期）が向上した。

　化合物 **56d** は化合物濃度 10 μM における CYP 阻害作用を評価した結果、7 種類の CYP（CYP1A2、2B6、2C19、2C8、2C9、2D6、3A4）に対して阻害作用を示さなかった（34%未満）。一方、同濃度におけるミラベグロン（**1**）の CYP 阻害作用評価を実施した結果、CYP2D6 に対して 87%の阻害作用を示した。ゆえに、化合物 **56d** はミラベグロン（**1**）よりも CYP2D6 にて代謝される薬に対して、薬物間相互作用のリスクが低いことが示唆された。

第5節　化合物 **56d** のラット心血管系への作用と排尿筋弛緩作用

　β₃-AR に高選択的で薬物動態プロファイルが改善した化合物 **56d** とミラベグロン（**1**）の心血管系の安全性プロファイルの比較を行った（Table 6）。ミラベグロン（**1**）を投与したラットは心拍数が増加し、平均血圧が大きく低下した。一方、化合物 **56d** を投与したラットはミラベグロン（**1**）と比べて心拍数や平均血圧の変動が少なかった。このデータは化合物 **56d** がミラベグロン（**1**）よりも心血管系への副作用が少なく、β₃-AR に高選択的であることがその要因であることを示唆している。

　次に、マーモセットを用いて化合物 **56d** の膀胱平滑筋に対する弛緩作用評価を実施した。Figure 7 に示すように、化合物 **56d** は事前に塩化カリウムで収縮させた膀胱平滑筋を用量依存的に弛緩させ、その最大薬効は陽性対象の非選択的β-AR アゴニストであるイソプロテレノールと同等であった。この結果から Figure 5 で示した化合物 **11** と同様にマーモセットの膀胱弛緩は高選択的β₃-AR アゴニスト **56d** の作用で十分に引き起こすことができると考えられ、その弛緩作用は蓄尿時の膀胱用量の増大につながると推定される。

　以上のように、β₃-AR に高選択的であり、経口投与可能で、薬物間相互作用のリスクが少なく、用量依存的に膀胱平滑筋の弛緩作用を示したので、化合物 **56d** は心血管系への副作用を軽減した過活動膀胱の治療薬になりえる有望化合物である。

第7節　第2章まとめ

　筆者は高活性、高選択的なβ₃-AR アゴニストである化合物 **56d** の創出に成功した。化合物 **56d** は用量依存的にマーモセットの膀胱平滑筋を弛緩させる優れた薬効を示し、臨床薬であるミラベグロンよりも心血管系の副作用が少なかった。さらに化合物 **56d** はミラベグロンよりも薬物間相互作用のリスクが低く、代謝的に安定であり、ラットにおいて十分な経口吸収が確認できた。ゆえに、化合物 **56d** は心血管系の副作用を軽減した過活動膀胱の治療薬として期待される。

第 3 章 β_3-AR と化合物 **56d** の相互作用解析

第 1 節　ドッキングスタディと分子動力学シミュレーションによるβ_3-AR と化合物 **56d** の結合様式の推定

　　第 1 章並びに第 2 章で述べたインダゾールシリーズβ_3-AR アゴニストとβ_3-AR とのドッキングスタディにより、結合様式を推定することはβ_3-AR アゴニスト活性の構造活性相関に対する理解とα_{1A}-AR、β_1-AR、β_2-AR に対する選択性を考察するために非常に有用である。β_3-AR の結晶構造は報告されていないため、β_3-AR のホモロジーモデルの構築を行う必要がある。これまでに、β_3-AR のサブタイプであるβ_2-AR のアンタゴニストもしくはインバースアゴニストとの複合体の結晶構造を基に、β_3-AR ホモロジーモデルを構築し、化合物の結合様式の解析並びに QSAR 解析を行った文献が報告されている。[14b, 14e, 35]一方、近年β_2-AR のアゴニストとの複合体の結晶構造が報告されたため、β_3-AR のホモロジーモデルとβ_3-AR アゴニストの推定結合様式を予測する精度向上が期待される。[36]ゆえに、私はβ_2-AR のアゴニストとの複合体の結晶構造（PDB entry 3P0G)を基にβ_3-AR ホモロジーモデルを構築することを計画した。Figure 8 にβ_3-AR ホモロジーモデルの構築からドッキングスタディまでの流れを示す。はじめに、β_1-AR、β_2-AR、β_3-AR 並びにα_{1A}-AR のアミノ酸配列は MOE 2015 のソフトウェアを用いてアライメントを実施した。さらにホモロジーモデルの鋳型となるβ_2-AR のアミノ酸配列に対しては Roy らの文献[35b]と同一のアライメントにした（Figure 9）。β_3-AR とβ_2-AR のアミノ酸配列の相同性は高く、56%であった。[35b]

　　続いて、インダゾールシリーズの中でβ_3-AR アゴニスト活性が最も高い化合物 **56f** とβ_3-AR ホモロジーモデルの複合体を構築した。次に、そのモデルを用いて 8 化合物のインダゾールシリーズと KUC-7322、化合物 **55** の 2 つの類縁体、並びにイソプロテレノールの合計 12 化合物を用いてドッキングスタディを実施した。同様のドッキングスタディの手順は当研究室においてヒスタミン H_3 受容体の結合様式解析で報告している。[37]ドッキングスコア（Glide XP）*と pEC_{50}†の相関解析を Figure 10 に示す。また、ドッキングスコアと pEC_{50} の値を Table 12 に示す。Figure 10 に示した通り、ドッキングスコアと pEC_{50} の間に正の相関が見られ、その相関係数（R）は $R = 0.67$ であり（Figure 10A）、8 つのインダゾール類縁体に限定すると $R = 0.90$ であった（Figure 10B）。ゆえに、ドッキングスコアと pEC_{50} の間には強い相関があることを示している。この強い相関はβ_3-AR ホモロジーモデルとリガンドのドッキングポーズによりβ_3-AR アゴニスト活性の構造活性相関を合理的に説明できる。

---

* リガンドとβ_3-AR の相互作用として水素結合、静電相互作用、ファンデルワールス力、クーロン力、疎水性相互作用に関してスコアを計算し、その合計からリガンドの配座安定性とリガンドの脱水和エネルギーをペナルティとして引いた値を最終的なドッキングスコアとして算出している

次に、インダゾールシリーズの中でβ₃-AR に対するアゴニスト活性、選択性、薬物動態プロファイルが最も良い化合物 **56d** とβ₃-AR のドッキングポーズに対して分子動力学（Molecular Dynamics, MD）シミュレーションによる解析を行った。なぜならば、ドッキングスコアが良好にもかかわらず、ドッキングにて得られたポーズと MD シミュレーション後に得られたポーズに大きく乖離がある例が報告されている[39]からである。Figure 11 に 20 ns 間の MD シミュレーション中、化合物 **56d** とβ₃-AR の主鎖 Cαの二乗平均偏差（Root Mean Square Deviation, RMSD）*の推移を示す。その結果、β₃-AR の構造、並びに化合物 **56d** の位置の RMSD は 1～3Å以内であり、さらに 5 ns～20 ns の間においてその値に変化が無く、安定な結合ポーズを定常的に保っていることが示唆された。ゆえに、20 ns の MD シミュレーション後の化合物 **56d** とβ₃-AR の結合様式に対して、詳細な相互作用解析を行った。
Figure 11. The plot showed the Root Mean Square Deviation (RMSD) evolution of β₃-AR (left *Y*-axis) and compound **56d** (right *Y*-axis). The RMSD was used to measure the average change in displacement of a selection of atoms for a particular frame with respect to a reference frame (the first frame was used as the reference and it is regarded as time *t*=0). 'Cα' shows the RMSD of Cα in β₃-AR backbone. 'Lig fit Prot' shows the RMSD of a ligand (**56d**) when the β₃-AR-**56d** complex is first aligned on the protein backbone of the reference and then the RMSD of the **56d** heavy atoms is measured. It was calculated for all frames in the trajectory.

* β₃-AR と化合物 **56d** のドッキングポーズを初期構造とし、MD シミュレーション中の各原子の二乗平均偏差を取ることで、初期構造からどのくらいβ₃-AR の構造や化合物 **56d** が動いたか示すことができる。

第 2 節　β₃-AR と化合物 **56d** の相互作用解析とβ₃-AR 選択性の考察

Figure 12 に 20ns MD シミュレーション後の化合物 **56d** とβ₃-AR の推定結合様式を示す。化合物 **56d** のアミノアルコールはβ₃-AR の Asp117、Asn332 と水素結合が確認された。また、化合物 **56d** のスルホンアミドNH は Ser208 と水素結合が確認された。これらの 3 つの水素結合は BI-167107-β₂-AR 複合体（PDB entry 3P0G）の結晶構造においても確認されており、アドレナリン受容体とアゴニストリガンドの間に重要な相互作用であると考えられている。さらに、化合物 **56d** のインダゾール NH と Cys196 の主鎖カルボニルの間に水素結合が見られ、インダゾール基の周辺は Leu97、Leu329、Trp333 との疎水性相互作用が予測された。また、化合物 **56d** のスルホンアミド基の酸素と Asn312 の間に水素結合が想定され、フェニル環と Phe309 との間に T 型のπ-π 相互作用が予測された。化合物 **56d** のシクロブタン基は Val118、Ile173、Tyr204 が形成する疎水性ポケットを占めていると推定された。

続いて、α₁ₐ-AR/β₃-AR の選択性に関して、化合物 **56d** とβ₃-AR の推定結合様式を基にβ₃-AR とα₁ₐ-AR のアミノ酸残基の違いから考察した。Figure 4 と Table 3 に示した通り、インダゾール 3 位置換基を変換した結果、α₁ₐ-AR に対するβ₃-AR 選択性の順番はイソプロピル **11** ＞ シクロブチル **14** ＞ エチル **10** ＞ メチル **5** ＞ ヒドロキシメチル **6** であった。この構造活性相関は疎水性相互作用がα₁ₐ-AR に対するβ₃-AR 選択性を高めることを示唆している。先に述べたように、インダゾール基はβ₃-AR の疎水性残基である Leu97、Leu329、Trp333 と相互作用している。一方、α₁ₐ-AR においてβ₃-AR の Leu329 に対応する残基は極性残基である Lys309 である。したがって、α₁ₐ-AR においてインダゾール環が相互作用しているポケットの環境はβ₃-AR よりもより極性が高いと推測される。ゆえに、α₁ₐ-AR/β₃-AR 選択性の構造活性相関は化合物 **56d** とβ₃-AR の推定結合ポーズから得られた結果を支持している。一方、スルホンアミド基の置換基を変えた時のα₁ₐ-AR に対するβ₃-AR 選択性の順番はフェニル **56f** ＞ シクロブチル **56d** ＞＞ *n*－プロピル **56a** ＞ メチル **5** であった（Table 8）。この構造活性相関はより嵩高い置換基がα₁ₐ-AR/β₃-AR 選択性を向上させていることを示す。化合物 **56d** のシクロブチル基はβ₃-AR の Val118、 Ile173、Tyr204 側鎖と疎水性相互作用をしている。一方、α₁ₐ-AR においてβ₃-AR の Ile173 に対応する残基は Leu162 である。さらに、スルホンアミド基のスルホンの近くにはβ₃-AR の細胞外第 2 ループ（Extracellular Loop 2, ECL2）に含まれる Phe198、Ala199、Ser200 があり、α₁ₐ-AR における対応する残基はそれぞれ Ile178、Asn179、Glu180 である。したがって、シクロブタンスルホンアミド基の置換基周辺はα₁ₐ-AR とβ₃-AR で対応する残基の種類が異なり、ポケットのサイズや水素結合に関する性質が違うため、その相互作用はα₁ₐ-AR とβ₃-AR の間で大きく異なると予想される。ゆえに、これらの違いが、スルホンアミド基の置換基を嵩高くした時にα₁ₐ-AR/β₃-AR 選択性が大きく向上することに関係していると推測される。

さらに、β₁-AR とβ₂-AR 対するβ₃-AR 選択性に関しても化合物 **56d** とβ₃-AR の推定結合ポーズを基に考察した。Edmondon らは化合物 **4** のアニリドのカルボニルがβ₃-AR の Ala197 の近傍にあり、その Ala197 はβ₁-AR とβ₂-AR における Asp 残基と対応し、静電的性質とサイズが異なる理由で化合物 **4** がβ₃-AR に高選択的であると報告している。[14b]化合物 **56d** のインダゾール NH はβ₃-AR の Cys196 の主鎖のカルボニルと水素結合しており、Ala197 はインダゾール基の近くに存在している。Edmondon らの報告と同様に、β₃-AR の Ala197 はβ₁-AR とβ₂-AR における Asp 残基と対応する（Asp217 in β₁-AR, Asp192 in β₂-AR）ため、この Asp 残基の側鎖は静電的性質とサイズが Ala197 と大きく異なる。ゆえに、化合物 **56d** のインダゾール基はβ₁-AR 並びにβ₂-AR と水素結合形成において不利に働くと推測される。したがって、このインダゾール基はβ₁-AR とβ₂-AR に対して高いβ₃-AR 選択性を有するために重要な置換基であると考えられる。

第３節　第３章まとめ

　β_3-AR のホモロジーモデルを作成し、12 種のβ_3-AR アゴニストとドッキングスタディを実施した。その結果、pEC$_{50}$とドッキングスコアに高い相関が確認できた。したがって、β_3-AR ホモロジーモデルとリガンドのドッキングポーズが妥当であることが示唆された。また、化合物 **56d** の MD シミュレーションを実施し、β_3-AR と化合物 **56d** は安定に結合していることが示唆された。化合物 **56d** とβ_3-AR の相互作用解析を実施し、さらにα_{1A}-AR 、β_1-AR 、β_2-AR に対するβ_3-AR 選択性に関して考察した。β_3-AR と化合物 **56d** の相互作用に重要なアミノ酸残基を明らかにしたことにより、今後、本成果は高選択的β_3-AR アゴニストの設計に有用な情報になり得る。

General Methods

  All reagents and solvents were purchased from commercial sources and were used as received. Anhydrous solvents were obtained from commercial sources. Thin layer chromatography (TLC) was carried out using the Merck GmbH Precoated silica gel 60 F254. Compounds were visualized by irradiation under a 254 nm UV light. Chromatography on silica gel was carried out using pre-packed silica gel cartridges (Yamazen Hi-Flash Column Silicagel or Purifpack-Si series) and the indicated solvent system on either a Yamazen Multi Prep YFLC or a Moritex Purif-α2 (50F). ^{1}H NMR spectra were recorded on either a JEOL AL-300 (300 MHz) or a Bruker BIOPIN AVANCE3HD (400 MHz), with chemical shifts reported in δ values (ppm) relative to trimethylsilane. The following abbreviations are used to describe peak patterns where appropriate: s; singlet, d; doublet, t; triplet, q; quartet, qu; quintet, dd; doublet doublet, td; triplet doublet, qd; quartet doublet, qud; quintet doublet, m; multiplet, and brs; broad singlet. Electrospray ionization (ESI) high-resolution mass spectra were recorded using a Thermo Fisher Orbitrap Velos Pro. Liquid chromatography-mass spectrometry (LC/MS) data were recorded using either a Micromass platform-LC type mass spectrometer or a Waters single quadrupole type mass spectrometer, the UPLC/SQD system, by an electrospray ionization (ESI) method. Human $β_1$-, $β_2$-, $β_3$ or marmoset $β_3$-AR Agonist Assay. The measurement of human $β_1$-, $β_2$-, $β_3$-, or marmoset $β_3$-AR agonist activity was carried out using stably transfected Chinese Hamster Ovary (CHO) cells expressing recombinant human $β_1$-, $β_2$-, or $β_3$-AR. The cells were cultured in Ham's F-12 medium containing 10% fetal bovine serum, 400 μg/mL geneticin (Invitrogen, Waltham, MA, USA), 100 U/mL penicillin, and 100 μg/mL streptomycin. Cells were seeded on a 96-well plate at a density of 2×10^4 cells/well and cultured for approximately 20 h. The medium was then aspirated from each well and replaced with 80 μL of serum-free Ham's F-12 medium, in which the cells were incubated for a further 15 min. The compound to be tested was initially dissolved in DMSO and then diluted with Ham's F-12 medium containing 100 mmol/L HEPES and 1 mmol/L isobutylmethylxanthine. The diluted compound (20 μL) was added to the cells and the cells were incubated with it for 30 min. The medium was removed and 0.1 mL of the Assay/Lysis Buffer from the cAMP-Screen kit (Applied Biosystems, Waltham, MA, USA) was added, and the cells were then incubated at 37 °C for 30 min. The cAMP level in the resulting cell lysate was quantified using the cAMP-Screen kit. The maximum response to the positive control, isoproterenol, was defined as 100%. The maximum response of each test compound was calculated as a percentage of this maximum response; this was defined as each compound's Intrinsic Activity [IA (%)]. The concentration of the compound that induced a response that was 50% of the maximum (EC_{50}) was also determined.

Rat β₃-AR Agonist Assay. The measurement of rat β_3 adrenergic receptor agonist activity was carried out using stably transfected Chinese Hamster Ovary (CHO) cells expressing recombinant rat β_3 adrenergic receptor. The cells were cultured in Ham's F-12 medium containing 10% fetal bovine serum, 400 μg/ml geneticin (Invitrogen), 100 U/ml penicillin and 100 μg/ml streptomycin. These cells were transfected with a cAMP-response element / luciferase reporter gene plasmid using the FuGENE 6 Tranfection Reagent (Roche). Transfected cells were seeded on a 96-well white plate at a density of 3×10^4 cells/well and were cultured for 20 hours. Following test compound addition to the cells and culture for a further 6 hours, the medium was removed. The PicaGene LT2.0 Luciferase Assay System solution (30 μL, Wako) was added to the cells, and chemiluminescence was analyzed using ARVOsx plate reader (PerkinElmer). The maximum response to the positive control isoproterenol was taken as 100%. The maximum response to each test compound was calculated as a percentage of the response of isoproterenol, and is termed the Intrinsic Activity [IA (%)]. The concentration of the compound solution that results in a response that was 50% of the maximum for that compound (EC_{50}) was determined.

Human α₁A-AR Agonist Assay. Human α_{1A}-AR agonist activity was measured using stably transfected HEK293 cells expressing recombinant human α_{1A}-AR. The cells were cultured in DMEM containing 10% fetal bovine serum, 400 μg/mL hygromycin B (Gibco BRL, Waltham, MA, USA), 100 U/mL penicillin, and 100 μg/mL streptomycin. Subsequently, the cells were prepared at a density of 5×10^6 cells/mL in a solution of Assay Buffer [20 mmol/L HEPES-KOH (pH 7.4), 115 mmol/L NaCl, 5.4 mmol/L KCl, 0.8 mmol/L MgCl₂, 1.8 mmol/L CaCl₂, 13.8 mmol/L D-glucose, and 0.1% bovine serum albumin] containing 0.2% Pluronic F-127 (Invitrogen) and 20 μmol/L Fura-2AM (Dojindo Laboratories, Kumamoto, Japan). The cells were incubated in a CO_2 incubator for 30 min, washed twice with the Assay Buffer to remove excess Fura-2AM, and resuspended at a density of 5×10^6 cells/mL with the Assay Buffer. Subsequently, the cells were dispensed into a 96-well plate at a volume of 80 μL/well. In addition to the cell plate, a sample plate was provided in which wells contained a test compound that had been diluted 10 times with the Assay Buffer to concentrations ranging from 10^{-5} to 10^{-12} M. The plates were loaded into an FDSS4000 kinetic plate reader (Hamamatsu Photonics K.K., Shizuoka, Japan), and were pre-incubated for 180 s at 37 °C. Fluorescence intensity (excitation wavelengths 340 nm and 380 nm, measurement wavelength 500 nm) was measured at intervals of 2 s. After baseline measurements were taken for approximately 30 s, 20 μL of the test sample from the sample plate was added to the cell plate, and measurements were collected for a further 270 s. The Ca^{2+} flux caused by the test compound was calculated as the peak height, which represented the difference between the maximum value of the fluorescence intensity ratio at wavelengths 340 nm and 380 nm after addition of the test compound, and the fluorescence intensity ratio at baseline. Maximum response to the positive control, noradrenaline, was defined as 100%. The maximum response to each test compound was calculated as a percentage of the maximum response to noradrenaline, and is termed the Intrinsic Activity [IA (%)]. The compound's EC_{50} was also determined.

Human α₁B or α₁D-AR Agonist Assay. Human α_{1B} or α_{1D}-AR agonist activity was measured using transiently transfected HEK293 cells expressing recombinant human α_{1B} or α_{1D}-AR, and NFAT-Luciferase reporter gene

(Stratagene, CA, USA). Cells were cultured in DMEM containing 10% fetal bovine serum, 100 U/mL penicillin and 100 μg/mL streptomycin. Cells were transfected using Lipofectamine 3000 Transfection Reagent (Life Technologies, CA, USA) according to the manufacture's protocol. Transfected cells were seeded on a 96-well white plate at a density of 1×10^5 cells/well and were cultured for 20 hours. Following test compound addition to the cells and culture for a further 6 hours, the medium was removed. The PicaGene LT2.0 Luciferase Assay System solution (30 μL, Wako, Osaka, Japan) was added to the cells, and chemiluminescence was analyzed using ARVOsx plate reader (PerkinElmer, MA, USA). The maximum response to the positive control noradrenaline was taken as 100%. The maximum response to each test compound was calculated as a percentage of the response of noradrenaline, and is termed the Intrinsic Activity [IA (%)]. The concentration of the compound solution that results in a response that was 50% of the maximum for that compound (EC_{50}) was determined The EC_{50} of noradrenaline for α_{1B}-AR and α_{1D}-AR was 359 nM and 101 nM, respectively.

Effects on Blood Pressure and HR in Rats. Male Sprague-Dawley rats (Japan SLC, Inc., Shizuoka, Japan) weighing 200-300 g were used. Rats were housed in an air-conditioned room (20-26 °C and 30-75% relative humidity with a 12-h light-dark cycle), fed a standard laboratory diet (CRF-1; Oriental Yeast, Tokyo, Japan), and given water ad libitum. Rats were anesthetized with sodium pentobarbital (50 mg/kg, i.p., and 25 mg/kg, s.c.). The left femoral vein and artery were exposed by a small incision. A polyethylene tube (SP10; Natsume Seisakusyo Co., Ltd., Tokyo, Japan) was inserted into the vein for injection of the compound. A polyethylene tube (SP31; Natsume Seisakusyo Co., Ltd.) was inserted into the artery and connected to a pressure transducer. Blood pressure was measured from the pressure transducer through a pressure amplifier (AP-641G; Nihon Koden Corp., Tokyo, Japan). HR was measured by the Heart Rate Counter (AT-601G; Nihon Koden Corp.), using the pulse wave of the blood pressure as the trigger. The blood pressure, MBP, and HR were recorded. Once the blood pressure and HR were almost constant, the test compound was administered through the left femoral vein and the parameters were recorded for 30 min. The maximum increase or decrease of HR and MBP is shown as a percentage change (%) relative to baseline.

Relaxant Activity on Isolated Marmoset Urinary Bladder Smooth Muscle. Three female common marmosets (*Callithrix jacchus*) aged 11-14 months were purchased from CLEA Japan Inc. (Tokyo, Japan) and were used between the ages of 19 and 20 months. Marmosets were housed in an air-conditioned room (27 ± 3 °C, 45 ± 15% humidity, 12-h light-dark cycle), fed 30 g daily of balanced marmoset food pellets (CMS-1; CLEA Japan), and given water ad libitum. Marmosets were anesthetized with an intramuscular injection of ketamine hydrochloride (15 mg/kg), and were sacrificed by exsanguination. The urinary bladder was carefully isolated and immersed in ice-cold Krebs–Henseleit solution that was gassed with 95% O_2 and 5% CO_2. The bladder was opened with a midline incision and six muscle strips of the bladder body, approximately 10-15 mm long and 2-5 mm wide, were prepared. The strips were suspended in a 10 mL glass organ bath filled with Krebs–Henseleit solution that was aerated with 95% O_2 and 5% CO_2 at 37 °C, and were allowed to equilibrate for over 30 min under a resting tension of 1 g. Strip tension was measured isometrically using a TB-612T force displacement transducer (Nihon Koden Corp.). Following the equilibration period, the strips were pre-contracted with KCl (40 mmol/L) three times and

strips that exhibited three equivalent contractions were used. These strips were again pre-contracted with 40 mmol/L KCl and, after the tension had stabilized, a test compound was added cumulatively at intervals of 20 min. When the relaxation response at the maximum concentration of the test compound was achieved, papaverine at a final concentration of 10^{-4} mol/L was added, and the maximum relaxation response of each strip was determined.

Solubility Assay. Stock solutions (10 mM) of each compound were prepared in DMSO, and 5 μL/well of the 10 mM stock solution was transferred into a 96-well plate. The plate was freeze-dried overnight, and to each well was added a pH 1.2 buffer solution (167 μL of Dissolution Test Solution 1, 11500-76; Kanto Chemical Co., Inc., Tokyo, Japan) or a pH 6.8 buffer solution (167 μL, Dissolution Test Solution 2 11499-76; Kanto Chemical Co., Inc.). The plate was sealed and shaken for over 18 h at 37 °C. Samples were filtered through a 0.4-μm multiscreen HTS-PCF filter plate (Millipore/Merck, Darmstadt, Germany) mounted on 96-well plate by centrifugation at 2000 rpm for 1 min at room temperature. Standards were created by initially preparing a 5 μL solution from the combination of the 10 mM stock solution and aqueous acetonitrile (162 μL, acetonitrile/water = 95:5) in a 96-well plate. The sample was then analyzed by HPLC. Water solubility was calculated according to the equation: Solubility (μM) = peak area$_{sample}$ / peak area$_{standard}$ x 300.

The HPLC analysis was performed with the following conditions: Waters ACQUITY UPLC BEH C18 column (1.7 μm, 2.1 x 50 mm), 40 °C; 0.6 mL/min flow rate; photodiode array detection (254 nm); solvent A consisting of 10 mM ammonium acetate in water; solvent B consisting of acetonitrile; a linear gradient of 5-98% B (2.5 min), 98% B (0.5 min), 5% B (1.5 min).

Madin-Darby Canine Kidney (MDCK) Permeability Assay. *In vitro* membrane permeability was determined using the MDCK cell monolayer system. The MDCK cell line (CCL-34™) was obtained from ATCC (Manassas, VA, USA). The cells were seeded on 24-well cell culture insert plates (Transwell, #3495; Corning, NY, USA) at a density of 3.32 x 10^5 cells/cm^2 and cultured for 4 days in Modified Eagle's Medium (MEM; Gibco, Waltham, MA, USA) to form monolayers. The MEM was changed once every 2-3 days. A buffer of Hanks' Balanced Salt Solution (HBSS), pH 7.4, with 25 mM HEPES and 10 mM glucose at 37 °C was used as the medium in the permeability study. The monolayers were rinsed twice with HBSS in both the donor (upper) and receiver (lower) compartments, and incubated in HBSS with 0.005% HCO 60 for 10 min to stabilize physiological parameters. During the transmembrane permeability experiments, the integrity of cell monolayers was assessed by transepithelial electrical resistance (TEER) measurements at fixed times using a tissue resistance measurement chamber (EVOM; World Precision Instruments, Sarasota, FL, USA). MDCK cell monolayers (TEER ≥ 600 Ω·cm^2) were washed in HBSS with 0.005% HCO60, and then a solution containing the test compound (50 μM) was added to the donor compartment, followed by an incubation at 37 °C for 60 min. The flux of test compound into the receiver compartment was measured with LC-MS/MS (Sciex, Foster City, CA, USA), and the apparent permeability coefficient (P_{app}) was calculated with the following equation: P_{app} (cm/s) = (dQ/dt) × 1/A × 1/C_0, where dQ/dt is the increase in the amount of drug in the receiver chamber per time interval, C_0 is the initial concentration in the donor compartment, and A is the permeability area of the cell culture insert. Three reference compounds were also screened: atenolol to represent paracellular transport; propranolol to represent efficient passive transcellular

transport; and methotrexate to represent poor passive transcellular transport. Atenolol and propranolol have a known human absorption of 50% and 90%, respectively, and can be used for ranking compounds with unknown characteristics.

LC-MS/MS Analysis. The LC-MS/MS system consisted of an Agilent 1100 series gradient HPLC pump (Agilent Technologies, Palo Alto, CA, USA), a CTC HTS PAL Autosampler (AMR, Inc., Tokyo, Japan) and a Sciex API 3200 triple quadrupole mass spectrometer (Sciex) equipped with a turbo ionspray interface. The samples were separated by reverse phase HPLC using a Capcell Pak MG III RP C18 50 × 2.1 mm column (Shiseido Inc., Tokyo, Japan). The compounds were analyzed with an optimized protocol within the following range of conditions: flow rate of 0.4mL/min [range: 0-0.7 min]; injection volume of 20 μL; solvent A consisting of 0.1% formic acid in water; solvent B consisting of acetonitrile; a linear gradient of 5%-90% B, 90% B (1.3 min), a return to initial conditions, and equilibration (1.5 min).

Human and Rat Unbound Microsomal Intrinsic Clearance Determination.

Human Microsomal Stability Assay. The incubation mixtures were prepared in 96-well cluster tubes (1.4 mL PP; Micronic, Aston, PA, USA). The metabolic stability of the test compounds was determined with pooled, mixed-gender human microsomes (pool of n = 50; XenoTech, Kansas City, KS, USA). Each reaction mixture consisted of 100 mM potassium phosphate buffer (pH 7.4), liver microsomes (final concentration, 0.5 mg/mL), NADPH regenerating mix (final concentration, 1.0 mM NADP+, 4.0 mM glucose-6-phosphate, 3.0 mM $MgCl_2$, 0.4 U/mL of glucose-6-phosphate dehydrogenase, 5.0 mM UDP-GA, and 0.165 mM β-NAD), and the test compound (1 μM) in a total volume of 100 μL. The incubation mixture was prewarmed for 5 min. Liver microsomes were added to the mixture, and kept in a shaking water bath for 15 min at 37 °C. To the mixture was added chilled acetonitrile (200 μL) containing an internal standard to stop the reaction. The samples were centrifuged at 3500 rpm for 15 min at 4 °C. The supernatants were analyzed by LC-MS/MS. Controls were prepared by omitting NADPH regenerating mix from the reaction mixture, and adding microsomes after the reaction was terminated.

Human Liver Microsomal Binding Assay. Microsomal binding of the test compounds was determined by equilibrium dialysis. Dialysis mixtures contained the test compound (1 μM), microsomal solution (final concentration of microsomes, 0.5 mg/mL; ratio of components = 1 : 1 : 8 [microsomes at 5 mg/mL : PBS, pH 7.4 : 125 mM phosphate buffer, pH 7.4]), in a final volume of 150 μL. Duplicate mixtures were subjected to equilibrium dialysis against 150 μL of 100 mM potassium phosphate buffer (pH 7.4) using 96-well Micro-Equilibrium Dialysis Devices (HT Dialysis LLC, Gales Ferry, CT, USA). The dialyzing unit consisted of two chambers separated by an ultrathin membrane with a molecular weight cut-off of 12-14 kDa. The plate was rotated at 300 rpm for 6 h at 37 °C in the plate shaker (Taitec Inc., Japan). Upon completion of the dialysis, 50 μL samples were obtained from the microsome and buffer sides. For a matrix composition match, 50 μL of 100 mM phosphate buffer (pH 7.4) was added to the microsome side sample and the microsome mixture was added to the buffer side sample. To the mixture was added chilled acetonitrile (300 μL) containing an internal standard to stop the reaction; the samples were then analyzed by LC-MS/MS. Results are expressed as the area ratio of each sample versus control: human microsome fu = peak area$_{sample}$ / peak area$_{control}$.

Rat Microsomal Stability Assay. The incubation mixtures were prepared in Corning 96-well cluster plates. The

metabolic stability of the test compounds was determined in pooled liver microsomes from male Sprague-Dawley rats (XenoTech). The reaction mixture consisted of 100 mM Tris-HCl buffer (pH 7.4), liver microsomes (5 mg/mL), NADPH regenerating mix (final concentrations of 0.165 mM NADP+, 4 mM glucose-6-phosphate, 3.0 mM MgCl$_2$, 0.1 U/mL of glucose-6-phosphate dehydrogenase, 5.0 mM UDP-GA, and 0.165 mM β-NAD), and the test compound (0.5 μM) in a total volume of 100 μL. Reactions were initiated by the addition of liver microsomes (final concentration, 0.5 mg/mL) and incubated in a shaking water bath for 20 min at 37 °C. To the mixture was added chilled acetonitrile (200 μL) containing an internal standard to stop the reaction. A control sample was prepared by adding acetonitrile to a reaction mixture lacking microsomes, and then adding microsomes after the reaction was terminated. The samples were centrifuged at 3500 rpm for 15 min at 4 °C. The supernatants were analyzed by LC-MS/MS.

Rat Liver Microsomal Binding Assay. Microsomal binding of the test compounds was determined by ultracentrifugation. Each ultracentrifugation mixture contained the test compound (0.5 μM), microsomal solution (final concentration, 0.5 mg/mL; ratio of components = 1 : 9 [microsomes at 5 mg/mL : 100 mM Tris-HCl buffer, pH 7.4]), in a final volume of 100 μL. Aliquots of 100 μL were placed in polyallomer ultracentrifuge tubes (8 mm × 34 mm; Beckman Coulter, Fullerton, CA, USA) and centrifuged at 160,000*g* for 16 h at 37 °C in an Optima TL ultracentrifuge (Beckman Coulter). Upon completion of the ultracentrifugation, 50 μL of the supernatant was obtained. To the supernatant was added chilled acetonitrile (50 μL) containing an internal standard to stop the reaction; the samples were then analyzed by LC-MS/MS. Controls were prepared by adding the test compound to the ultracentrifugal supernatant of the microsomal solution. Results are expressed as the area ratio of sample versus control: rat microsome fu = peak area$_{sample}$ / peak area$_{control}$.

LC-MS/MS Analysis. The LC-MS/MS system consisted of an Agilent 1100 series gradient HPLC pump (Agilent Technologies, Palo Alto, CA, USA), a CTC HTS PAL Autosampler (AMR, Inc., Tokyo, Japan), and a Sciex API 3200 triple quadrupole mass spectrometer (Sciex, Foster City, CA, USA) equipped with a turbo ionspray interface. The samples were separated by reverse phase HPLC using an Inert Sustain RP C18 50 × 2.1 mm column (GL Science Inc., Tokyo, Japan) or Capcell Pak RP C18 50 × 2.1 mm column (Shiseido Inc., Tokyo, Japan). The compounds were eluted with an optimized gradient, which fell within the following method conditions: flow rate of 0.4 mL/min (range: 0-0.7 min); injection volume of 20 μL; solvent A consisting of 0.1% formic acid in water; solvent B consisting of acetonitrile or 0.1% formic acid in acetonitrile; the percentage of B was linearly increased from 5% to 90%, 90% B (1.3 min), returned to initial conditions, equilibrated (1.5 or 1.6 min). The area ratio of each test compound was calculated by comparing the peak area of the compound to the peak area of an internal standard.

Calculation of Human and Rat Unbound Microsomal Intrinsic Clearance (hCL$_{int,u}$ and rCL$_{int,u}$). Metabolic stability was determined by plotting the natural logarithm of the concentration of unchanged test compound as a function of time. The first-order rate constant was calculated using the equation k = [Ln(C$_0$) − Ln(C)]/incubation time, where C$_0$ was the initial concentration of the test compound, C was the concentration of the test compound remaining after incubation (C = C$_0$ × remaining ratio), and the incubation time was 15 min (human) or 20 min (rat). The half-life (t$_{1/2}$) was estimated using the equation t$_{1/2}$ = 0.693/k. The hCL$_{int,u}$ was estimated using the equation hCL$_{int,u}$ = k/(microsomal protein concentration) × (microsomal protein per gram of liver) × (liver mass per kilogram of body

mass) / (human microsome fu), where k was the first-order rate constant, the microsomal protein concentration was 0.5 mg/mL, the microsomal protein per gram of liver was 48.8 mg, the liver mass per kilogram of body mass was 25.7 g, and the human microsome fu was determined experimentally from the human liver microsomal binding assay.[40] The $rCL_{int,u}$ was estimated using the equation $rCL_{int,u}$ = k / (microsomal protein concentration) × (microsomal protein per gram of liver) × (liver mass per kilogram of body mass) / (rat microsome fu), where k was the first-order rate constant, the microsomal protein concentration was 0.5 mg/mL, the microsomal protein per gram of liver was 44.8 mg, liver mass per kilogram of body mass was 40.0 g, and the rat microsome fu was determined experimentally from the rat liver microsomal binding assay.[40]

PK Study. Compounds **5**, **11**, and **56d** were subjected to PK studies in male Sprague-Dawley rats. Test compounds were administered orally to rats (n = 2 or 3) at a dose of 5 mg/kg in saline or water (dose volume 5 mL/kg). Blood samples were collected via the subclavian vein at 0.5, 1, 2, 4, 6, and 8 h post dose. Plasma was separated by centrifugation and stored frozen at -20 °C until analysis. Plasma compound concentrations were determined using LC-MS/MS. PK parameters were calculated using the non-compartmental analysis tool provided with WinNonlin® Enterprise software v6.4.0.768 (Certara, Princeton, NJ, USA).

Cytochrome P450 Inhibition Assay. CYP inhibition assays (CYP1A2, 2B6, 2C19, 2C8, 2C9, 2D6, and 3A4) were performed with Promega assay kits (P450-Glo™ Assays; Madison, WI, USA) according to the manufacturer's instructions.

In silico

Homology Modeling of the β₃-AR. The β₃-AR sequence was aligned with the human β₂-AR sequence.[35b] A three-dimensional model of the β₃-AR was constructed using Prime in the Maestro software (Schrödinger, LLC). Because it is very long and was predicted to be disordered, the third intracellular loop was truncated by five residues leading into TM6.

Docking Study. Energy minimization and protonation of all compounds was performed with LigPrep in the Maestro software (Schrödinger, LLC). Docking of the compounds into the β₃-AR model utilized three main steps that take into account several levels of structural flexibility and scoring criteria: (1) molecular modeling of compound-bound β₃-AR by docking compound **56f**, with consideration of both ligand and receptor flexibility; (2) rigid receptor docking of eight indazole analogues and four other series into the active site of the compound **56f**-bound β₃-AR model generated in the previous step; (3) rescoring according to the calculated binding score (Glide extra precision, XP; Schrödinger, LLC).

In order to account for both compound and receptor flexibility in the first step, the Glide "Induced Fit Docking (IFD)" protocol (Schrödinger, LLC) was utilized, followed by iteratively combining rigid receptor docking (Glide) and protein remodeling by side chain searching and minimization (Prime) techniques. Hydrogen-bonding constraints between the side chain COO⁻ group of Asp117 and the side chain C=O group of Asn332 were introduced, because this hydrogen-bonding formation is highly conserved in almost all known complexes formed

75

between members of the β-AR family bound to isoproterenol and a wide variety of agonists. In the protein remodeling stage, all residues within a 5 Å radius of each initial docked compound were refined using Prime. The compound was then redocked into the refined receptor structure using Glide in the standard precision (SP) mode. All the docked structures were then ranked according to Glide score. After modeling the compound-β_3-AR complex using the IFD protocol, grid generation and rigid receptor docking of the eight indazole analogues and four other series using Glide (SP mode) was conducted, using hydrogen-bonding constraint to connect the side chain oxygen atom of Ser208. The best orientation for each docked compound was rescored according to its binding score (Glide XP; Schrödinger, LLC).

MD simulation. The compound **56d**-bound structure of human β_3-AR was subjected to 20 ns MD simulations using Desmond version 2.3[41] with OPLS3 force field[42]. The initial model structure was placed into a large palmitoyloleoylphosphatidylcholine (POPC) bilayer at a depth consistent with the structure of human β_2-AR with BI-167107 (PDB entry 3P0G) from the Orientation of Proteins in Membranes (OPM) database[43] and TIP3P water molecules solvated with 0.15 M NaCl. After minimization and relaxation of the model, the production MD phase was performed for 20 ns in the isothermal-isobaric (NPT) ensemble at 300 K and 1 bar using Langevin dynamics. Long-range electrostatic setups were performed using Maestro (Schrödinger, LLC).
