Hokkaido University Collection of Scholarly and Academic Papers: HUSCAP
Projections of surfaces in the hyperbolic space along horocycles

Shyuichi Izumiya and Farid Tari

January 9, 2008

Abstract

We study in this paper orthogonal projections of embedded surfaces $M$ in $H^3_3(-1)$ along horocycles to planes. The singularities of the projections capture the extrinsic geometry of $M$ related to the lightcone Gauss map. We give geometric characterisations of these singularities and prove a Koenderink type theorem which relates the hyperbolic curvature of the surface to the curvature of the profile and of the normal section of the surface. We also prove duality results concerning the bifurcation set of the family of projections.

1 Introduction

The work of this paper is part of a wider project of investigating the extrinsic geometry of submanifolds embedded in the pseudo-spheres in the Minkowski space $\mathbb{R}^{n}_{1}$ via singularity theory. The extrinsic geometric information is obtained by considering the contact of the submanifold with degenerate objects in the given pseudo-sphere. By degenerate we mean, for instance, a flat object (that is, a submanifold with some curvature vanishing everywhere).

We studied in [27] the contact of surfaces in the hyperbolic space with geodesics. This is measured by the singularities of orthogonal projections of the surface along geodesics to hyperplanes and horospheres. The expression of an orthogonal projection along a geodesic is also given in [28] using a different method. The work in [27] is analogous to that on orthogonal projections of surfaces in the Euclidean and projective 3-spaces (these are well studied; see for example [1, 3, 4, 6, 7, 9, 11, 29, 30, 32, 33, 34, 2000 Mathematics Subject classification 53A35, 58K05.

Key Words and Phrases. Bifurcation sets, contours, Legendrian duality, projections, profiles, hyperbolic space, singularities, de Sitter space, lightcone.)
35]). Analogous in [27] means that we view a line in the Euclidean space as a geodesic. But a line in the Euclidean space can also be viewed as the limit of circles with radii tending to infinity. In the hyperbolic space, the limit of circles with radii tending to infinity is a horocycle. So it is natural to consider, as we do in this paper, projections in the hyperbolic space along horocycles.

Another reason we consider projections along horocycles is the following. Given \(p \in M\), there is a well defined unit normal vector \(e(p)\) to \(M\) at \(p\); see §2. (If \(M\) is orientable, then \(e(p)\) is globally defined. However, it is always locally defined and our investigation here is local in nature.) The vector \(e(p)\) is in the de Sitter space \(S^3_{1}\) and we have the de Sitter Gauss map

\[
E : M \rightarrow S^3_{1} \\
p \rightarrow e(p)
\]

The projections of \(M\) along geodesics pick up extrinsic geometric information about \(M\) related to the de Sitter Gauss map, see [27]. For example, the projection along a geodesic has a cusp singularity at \(p\) if and only if the tangent to the geodesic at \(p\) is a de Sitter asymptotic direction. The points on \(M\) where the projection has a swallowtail singularity is precisely the locus of points of geodesic inflections of the de Sitter asymptotic curves. Also, the projection has a lips/beaks singularity at \(p\) if and only if \(p\) is a de Sitter parabolic point and the tangent to the geodesic is along the unique de Sitter asymptotic direction at \(p\).

There is another Gauss map on the surface introduced in [19] and called the lightcone Gauss map; see §2. The vector \(p \pm e(p)\) is lightlike (i.e., belongs to the lighcone \(LC^*\)), so we have the lightcone Gauss maps

\[
L^\pm : M \rightarrow LC^* \\
p \rightarrow p \pm e(p)
\]

Projecting along horocycles is a natural candidate to pick up extrinsic geometric information about the surface related to the lightcone Gauss map. We expect, for instance, the projection along a horocycle with tangent at \(p\) along a horo-asymptotic direction (i.e., a direction \(u\) satisfying \(\langle d_p(L^\pm)(u), u \rangle = 0\)) to have a cusp singularity at \(p\).

We give in §3 the expression of the family \(P\) of projections along horocycles to orthogonal planes. The planes of projection are arbitrary, that is, projecting to parallel orthogonal planes yields the same information. So we project to the planes that passe through the point \(p_0 = (1, 0, 0, 0)\). Then the horocycles of interest are determined by a pair of vectors \((l, v)\) in the set \(C = \{(l, v) \in S^2_+ \times S^2_0 \mid \langle l, v \rangle = 0\}\), where \(S^2_+\) and \(S^2_0\) are spheres in \(LC^*\) and \(S^3_1\) respectively. The set \(C\) is in fact the parameter space of our family of projections. For \((l, v)\) fixed, the map \(P_{(l,v)}\) can be considered locally as a map-germ from \(\mathbb{R}^2, 0 \rightarrow \mathbb{R}^2, 0\). We show in §4 that \(P_{(l,v)}\) has a cusp singularity or worse if and only if \(\kappa(v^*) = -\langle l, e(p) \rangle / \langle l, p \rangle\), where \(v^*\) is the tangent to the horocycle \((l, v)\)
at $p$ and $\kappa(v^*)$ is the de Sitter normal curvature at $p$ along $v^*$. The above relation yields several interesting geometric properties of $M$ (Theorem 4.2). For instance, $\kappa(v^*) = \pm 1$ if and only if $v^*$ is a horo-asymptotic direction and $\ell = \widetilde{L}^\pm(p)$, where $\widetilde{L}^\pm(p)$ is the radial projection of $L^\pm(p)$ to $S^2_\pm$. We also show that the points $p \in M$ where the projection along the horocycle $(\widetilde{L}^\pm(p), v)$ has a swallowtail singularity at $p$ is precisely the locus of geodesic inflections of the horo-asymptotic curves (Proposition 4.3). We then prove a Koenderink type theorem which relates the hyperbolic curvature of the surface to the curvature of the profile and of the normal section of the surface (Theorem 4.4).

We prove in §5 a duality result between some surfaces associated to $M$ and some special curves on the $\Delta_2$-dual surface $M^{(2)}$ of $M$; (see §6). The result is analogous to that of Shcherback in [34]. We also prove a duality result concerning the bifurcation sets of the families of projections, analogous to that of Bruce-Romero Fuster in [9]. In §5, we use the duality concepts introduced in [13, 14]; see §6 for details.

2 Preliminaries

The Minkowski space $(\mathbb{R}^4_1, \langle \cdot, \cdot \rangle)$ is the 4-dimensional vector space $\mathbb{R}^4$ endowed with the pseudo scalar product $\langle x, y \rangle = -x_0y_0 + \sum_{i=1}^3 x_iy_i$, where $x = (x_0, x_1, x_2, x_3)$ and $y = (y_0, x_1, x_2, y_3)$ in $\mathbb{R}^4$. We say that a vector $x$ in $\mathbb{R}^4_1 \setminus \{0\}$ is spacelike, lightlike or timelike if $\langle x, x \rangle > 0$, $= 0$ or $< 0$ respectively. The norm of a vector $x \in \mathbb{R}^4_1$ is defined by $\|x\| = \sqrt{|\langle x, x \rangle|}$.

Given a vector $v \in \mathbb{R}^4_1$ and a real number $c$, the hyperplane with pseudo normal $v$ is defined by $HP(v, c) = \{x \in \mathbb{R}^4_1 | \langle x, v \rangle = c\}$.

We say that $HP(v, c)$ is a spacelike, timelike or lightlike hyperplane if $v$ is timelike, spacelike or lightlike respectively. We have the following three types of pseudo-spheres in $\mathbb{R}^4_1$:

- **Hyperbolic 3-space**: $H^3(-1) = \{x \in \mathbb{R}^4_1 | \langle x, x \rangle = -1\}$,
- **de Sitter 3-space**: $S^3_1 = \{x \in \mathbb{R}^4_1 | \langle x, x \rangle = 1\}$,
- **(open) lightcone**: $LC^* = \{x \in \mathbb{R}^4_1 \setminus \{0\} | \langle x, x \rangle = 0\}$.

We also define the lightcone sphere

$$S^2_+ = \{x \in LC^* | \langle x, x \rangle = 0, x_0 = 1\}$$

and the Euclidean sphere

$$S^2_0 = \{x \in S^3_1 | \langle x, x \rangle = 1, x_0 = 0\}.$$

For $x \in LC^*$, we have $x_0 \neq 0$ so

$$\tilde{x} = \left(1, \frac{x_1}{x_0}, \frac{x_2}{x_0}, \frac{x_3}{x_0}\right) \in S^2_+.$$
The hyperbolic space has two connected components. We only consider embedded surfaces in $H^4_+(-1) = \{x \in H^3(-1) | x_0 \geq 1\}$ as the study is similar for those embedded in $H^3(-1) = \{x \in H^3(-1) | x_0 \leq -1\}$.

The wedge product of 4 vectors $a_1, a_2, a_3 \in \mathbb{R}^4_1$ is given by

$$a_1 \wedge a_2 \wedge a_3 = \begin{vmatrix} -e_0 & e_1 & e_2 & e_3 \\ a_1^0 & a_1^1 & a_1^2 & a_1^3 \\ a_2^0 & a_2^1 & a_2^2 & a_2^3 \\ a_3^0 & a_3^1 & a_3^2 & a_3^3 \end{vmatrix},$$

where $\{e_0, e_1, e_2, e_3\}$ is the canonical basis of $\mathbb{R}^4_+$. One can check that $(a, a_1 \wedge a_2 \wedge a_3) = \det(a, a_1, a_2, a_3)$, so the vector $a_1 \wedge a_2 \wedge a_3$ is pseudo orthogonal to all the vectors $a_i$, $i = 1, 2, 3$.

Some aspects of the extrinsic geometry of hypersurfaces in the hyperbolic space are studied in [13]–[23] and [26, 27]. Let $M$ be a surface embedded in $H^4_+(-1)$. Given a local chart $\mathbf{i} : U \rightarrow M$, where $U$ is an open subset of $\mathbb{R}^2$, we denote by $\mathbf{x} : U \rightarrow H^4_+(-1)$ such embedding, identify $\mathbf{x}(U)$ with $U$ through the embedding $\mathbf{x}$ and write $M = \mathbf{x}(U)$. Since $\langle \mathbf{x}, \mathbf{x} \rangle \equiv -1$, we have $\langle \mathbf{x}_{u_i}, \mathbf{x} \rangle \equiv 0$, for $i = 1, 2$, where $u = (u_1, u_2) \in U$. We define the spacelike unit normal vector $\mathbf{e}(u)$ to $M$ at $\mathbf{x}(u)$ by

$$\mathbf{e}(u) = \frac{\mathbf{x}(u) \wedge \mathbf{x}_{u_1}(u) \wedge \mathbf{x}_{u_2}(u)}{\|\mathbf{x}(u) \wedge \mathbf{x}_{u_1}(u) \wedge \mathbf{x}_{u_2}(u)\|}.$$  

It follows that the vector $\mathbf{x} \pm \mathbf{e}$ is a lightlike vector. Let

$$\mathbf{E} : U \rightarrow S^0_+ \text{ and } \mathbf{L}^\pm : U \rightarrow LC^*$$

be the maps defined by $\mathbf{E}(u) = \mathbf{e}(u)$ and $\mathbf{L}^\pm(u) = \mathbf{x}(u) \pm \mathbf{e}(u)$. These are called, respectively, the de Sitter Gauss map and the lightcone Gauss map (or hyperbolic Gauss indicatrix) of $M$ ([19]). For any $p = \mathbf{x}(u_0) \in M$ and $v \in T_pM$, one can show that $D_v\mathbf{E} \in T_pM$, where $D_v$ denotes the covariant derivative with respect to the tangent vector $v$. Since the derivative $d\mathbf{x}(u_0)$ can be identified with the identity mapping $1_{T_pM}$ on the tangent space $T_pM$, we have $d\mathbf{L}^\pm(u_0) = 1_{T_pM} \pm d\mathbf{E}(u_0)$, under the identification of $U$ and $M$ via the embedding $\mathbf{x}$.

The linear transformation $A_p = -d\mathbf{E}(u_0)$ is called the de Sitter shape operator. Its eigenvalues $\kappa_i$, $i = 1, 2$, are called the de Sitter principal curvature and the corresponding eigenvectors $p_i$, $i = 1, 2$, are called the de Sitter principal directions.

The linear transformation $S_p^\pm = -d\mathbf{L}^\pm(u_0)$ is labeled the lightcone shape operator of $M$ at $p$. It has the same eigenvalues as $A_p$, but its eigenvalues are distinct from those of $A_p$. In fact the eigenvalues $\bar{\kappa}_i^\pm$ of $S_p^\pm$ satisfy $\bar{\kappa}_i^\pm = -1 \pm \kappa_i$, $i = 1, 2$.

We call $K_e(p) = \det(A_p) = \kappa_1(p)\kappa_2(p)$ (resp. $K_h(p) = \det(S_p^\pm) = \bar{\kappa}_1(p)\bar{\kappa}_2(p)$) the de Sitter (resp. hyperbolic) Gauss-Kronecker curvature of $M$ at $p$. The curvature $K_e$ is also called the extrinsic Gaussian curvature. The set of points where $K_e(p) = 0$ (resp.
$K_{h}^{\pm}(p) = 0$) is labelled the de Sitter (resp. horospherical, horo- for short) parabolic set of $M$. The restriction of the pseudo-scalar product to the hyperbolic space is a scalar product, so $H_{3}^{3}(-1)$ is a Riemannian manifold. We have the sectional curvature $K_{I}$ of $M$ which is also called the intrinsic Gaussian curvature. It is known that $K_e = K_I + 1$ (see §2.2 in [10]).

The operators $A_p$ and $S_p^{\pm}$ are self-adjoint operators on $M$, so we can define the notion of asymptotic directions at $p$. We say that $u \in T_pM$ is a de Sitter (resp. horo-) asymptotic direction if and only if $\langle A_p(u), u \rangle = 0$ (resp. $\langle S_p^{\pm}(u), u \rangle = 0$). There are $0/1/2$ de Sitter (resp. horo-) asymptotic directions at every point where $K_e(p)$ (resp. $K_{h}(p)$) $0 > /= < 0$.

We also define the de Sitter normal curvature at $p$ along a direction $u \in T_pM$ to be $\kappa(u) = \langle A_p(u), u \rangle / \langle u, u \rangle$. The horo-normal curvature at $p$ along a direction $u \in T_pM$ is defined similarly and is given by $\kappa_{h}^{\pm}(u) = \langle S_p^{\pm}(u), u \rangle / \langle u, u \rangle$.

A surface given by the intersection of $H_{3}^{3}(-1)$ with a spacelike, timelike or lightlike hyperplane is called respectively sphere, equidistant surface or horosphere. The intersection of the surface with timelike hyperplane through the origin is called simply a plane. Planes are the only surfaces with everywhere zero de Sitter Gaussian curvature ([21]). Horospheres are the only surfaces with everywhere zero hyperbolic curvature ([21]).

3 The family of projections along horocycles

We need some preliminaries about curves in $H_{3}^{3}(-1)$. Let $\gamma : I \rightarrow H_{3}^{3}(-1)$ be a regular curve. Since $H_{3}^{3}(-1)$ is a Riemannian manifold, we can parametrise $\gamma$ by arc-length and assume that $\gamma(s)$ is unit speed. Let $t(s) = \gamma'(s)$, with $||t(s)|| = 1$. The vector $t'(s)$ is not in the tangent space $T_{\gamma(s)}H_{3}^{3}(-1)$, so we project it along $\gamma$ to this tangent space. The resulting vector is $t'(s) - \gamma(s)$. Now if $\langle t'(s), t'(s) \rangle \neq -1$, then $||t'(s) - \gamma(s)|| \neq 0$. In this case, we define the unit normal vector to the curve as the vector $n(s) = \frac{t'(s) - \gamma(s)}{||t'(s) - \gamma(s)||}$. If $e(s) = \gamma(s) \wedge t(s) \wedge n(s)$, then we have a pseudo orthogonal frame $\{\gamma(s), t(s), n(s), e(s)\}$ in $\mathbb{R}_{3}^{4}$ along $\gamma$. Frenet-Serret type formulae, similar to those for a space curve in $\mathbb{R}^{3}$, can be proved for the curve $\gamma$ ([22]) and are as follows

\[
\begin{aligned}
\gamma'(s) &= t(s) \\
\gamma''(s) &= \gamma(s) + \kappa_{h}(s)n(s) \\
n'(s) &= -\kappa_{h}(s)t(s) + \tau_{h}(s)e(s) \\
e'(s) &= -\tau_{h}(s)n(s)
\end{aligned}
\]

where $\kappa_{h}(s) = ||t'(s) - \gamma(s)||$ and $\tau_{h}(s) = -\det(\gamma(s), \gamma'(s), \gamma''(s), \gamma'''(s))/\kappa_{h}(s)^{2}$. The quantities $\kappa_{h}(s)$ and $\tau_{h}(s)$ are called the curvature (resp. torsion) of the curve $\gamma$ at $\gamma(s)$. The condition $\langle t'(s), t'(s) \rangle \neq -1$ above is in fact equivalent to $\kappa_{h}(s) \neq 0$. (See
When the curve $\gamma$ is not parametrised by arc length, the formula for the curvature is

$$\kappa_h(\theta) = \left|\frac{1}{l'(\theta)^3} (\gamma''(\theta)l'(\theta) - \gamma'(\theta)l''(\theta)) - \gamma(\theta)\right|,$$

where

$$l(\theta) = \int_0^\theta ||\gamma'(\alpha)||d\alpha.$$

A horocycle in $H^3_+(-1)$ is the intersection of a horosphere with a plane orthogonal to the horosphere. Let $HS^3(l, c) = H^3_+(-1) \cap HP(l, c)$, with $l \in S^2_+ \subset LC^*$ and $c \in \mathbb{R}$, denote a horosphere in $H^3_+(-1)$. Then a horocycle is given by $HS^3(l, c) \cap HP(v, 0)$, with $v \in S^3_1$ and $\langle l, v \rangle = 0$. Fixing $l$ and $v$ and varying $c$ gives parallel horocycles.

A smooth curve in $H^3_+(-1)$ is a horocycle if and only if $\kappa_h \equiv 1$ and $\tau_h \equiv 0$ ([18]). Also, for a curve in a hyperbolic plane (which is the case of a horocycle), $\kappa_g$ denotes its geodesic curvature, and the hyperbolic curvature $K_h = \kappa_g - 1 = \kappa_h - 1$. Therefore, for a horocycle we have $K_h \equiv 0$, which means that they are flat objects.

We are considering here orthogonal projections along horocycles to planes. Projecting to two parallel planes yields the same information, so we choose those that pass through the point $p_0 = (1, 0, 0, 0)$. These are parametrised by the sphere $S^2_0$. So parallel horocycles in $H^3_+(-1)$ that are of interest are those determined by the elements of the set

$$C = \{(l, v) \in S^2_+ \times S^2_0 \mid \langle l, v \rangle = 0\}.$$

Given a plane $HP(v, 0) \cap H^3_+(-1)$, with $v \in S^2_0$, and a point $p \in H^3_+(-1)$, there is a unique horocycle through $p$, determined by a unique $(l, v) \in C$, which intersects orthogonally the given plane at some point $q(p, (l, v))$. We call the point $q(p, (l, v))$ the orthogonal projection of $p$ along the horocycle $(l, v)$.

Let $\pi : C \to S^2_0$ be the projection $\pi(l, v) = v$ and $i : S^3_0 \to S^3_1$ be the inclusion $i(v) = v$. Let

$$\mathcal{F} = \{(v, w) \in TS^3_1 \mid \langle w, w \rangle = -1\} \to S^3_1$$

be the timelike unit spherical bundle over $S^3_1$.

**Theorem 3.1** The family of projections along horocycles in $H^3_+(-1)$ is given by

$$P : H^3_+(-1) \times C \to (i \circ \pi)^* \mathcal{F}$$

$$(p, (l, v)) \mapsto ((l, v), q(p, (l, v)))$$

where

$$q(p, (l, v)) = p - \langle p, v \rangle v + \frac{1}{2} \frac{\langle p, v \rangle^2}{\langle p, l \rangle} l.$$
Proof. A parametrisation of the horocycle \((l, v)\) which is orthogonal to the plane \(HP(v, 0) \cap H^3_{\pm}(1)\) at \(q(p, (l, v))\) is given by

\[
c(s) = q(p, (l, v)) + sv + \frac{s^2}{2} \lambda l.
\]

for some scalar \(\lambda\), see [24]. The horocycle \(c(s)\) passes through \(p\) if \(p = q(p, (l, v)) + s_0v + \frac{s_0^2}{2} \lambda l\) for some \(s_0 \in \mathbb{R}\). So \(q(p, (l, v)) = p - s_0v - \frac{s_0^2}{2} \lambda l\). We have

\[
\langle q(p, (l, v)), v \rangle = \langle p, v \rangle - s_0 = 0,
\]

which gives \(s_0 = \langle p, v \rangle\). As \(c(s_0) \in H^3_{\pm}(1), \langle c(s_0), c(s_0) \rangle = -1\), we have

\[
\langle q(p, (l, v)), \lambda l \rangle = \langle p, \lambda l \rangle = -1,
\]

therefore \(l = -1/(p, l)\). Hence \(q(p, (l, v)) = p - \langle p, v \rangle v + \frac{1}{2} \frac{\langle p, v \rangle^2}{(p, l)} l\). 

In this paper, the family of orthogonal projections of a given surface \(M\) in \(H^3_{\pm}(1)\) along horocycles refers to the restriction of the family \(P\) to \(M\). We still denote this restriction by \(P\). We have the following result where the term generic is defined in terms of transversality to submanifolds of multi-jet spaces (see for example [12]).

**Theorem 3.2** For a residual set of embeddings \(x : M \rightarrow H^3_{\pm}(1)\), the family \(P\) is a generic family of mappings.

**Proof.** The theorem follows from Montaldi’s result in [31] and the fact that \(P : H^3_{\pm}(1) \times C \rightarrow (i \circ \pi)^* \mathcal{F}\) is a stable map. 

We denote by \(P_{(l,v)}\) the map \(H^3_{\pm}(1) \rightarrow H^3_{\pm}(1)\), given by \(P_{(l,v)}(p) = q(p, (l, v))\), with \(q(p, (l, v))\) as in Theorem 3.1. We also keep the same notation for the restriction of \(P_{(l,v)}\) to the surface \(M \subset H^3_{\pm}(1)\).

For a given \((l, v) \in C\) and a point \(p_0 \in M\), one can choose local coordinates so that \(P_{(l,v)}\) restricted to \(M\) can be considered locally as a map-germ \(\mathbb{R}^3, 0 \rightarrow \mathbb{R}^2, 0\). These map-germs are extensively studied. We refer to [32] for the list of the \(\mathcal{A}\)-orbits with \(\mathcal{A}_r\)-codimension \(\leq 6\), where \(\mathcal{A}\) denotes the Mather group of smooth changes of coordinates in the source and target. In Table 1, we reproduce from [32] the list of local singularities of \(\mathcal{A}_r\)-codimension \(\leq 3\). Some of these singularities are also called as follows: \(4_2\) (lips/beaks), \(4_3\) (goose), \(5\) (swallowtail), \(6\) (butterfly), \(11_5\) (gulls).

It follows from Theorem 3.2 that for generic embeddings of the surface only singularities of \(\mathcal{A}_r\)-codimension \(\leq \dim(C) = 3\) can occur in the members of the family of orthogonal projections. So we have the following result.

**Proposition 3.3** For a residual set of embeddings \(x : M \rightarrow H^3_{\pm}(1)\), the projections \(P_{(l,v)} : M \rightarrow H^3_{\pm}(1)\) in the family \(P\) have local singularities \(\mathcal{A}\)-equivalent to one in Table 1 whose \(\mathcal{A}_r\)-codimension \(\leq 3\). Moreover, these singularities are versally unfolded by the family \(P\).
Table 1: $\mathcal{A}_c$-codimension $\leq 3$ local singularities of map-germs $\mathbb{R}^2, 0 \to \mathbb{R}^2, 0$ ([32]).

The members of $P$ can also have multi-local local singularities with $\mathcal{A}_c$-codimension $\leq 3$, and these singularities are also versally unfolded by the family $P$. However, in this paper, we deal mainly with the geometry of the local singularities.

4 Characterisations of the singularities of $P_{(l,v)}$

Given $(l, v) \in \mathcal{C}$ and a point $p \in M$, we denote by $v^*$ the tangent at $p$ to the horocycle through $p$ and $q(p, (l, v))$. Then

$$v^* = c'(s_0) = v - \frac{(p, v)}{(p, l)}l,$$

where $c(s)$ and $s_0$ are as in the proof of Theorem 3.1. Let $S_p^2 = T_p H_+^3(-1) \cap S^3_1$, $\mathcal{C}_p = \{(l, w) \in S_p^2 \times S_p^2 | (l, w) = 0\}$ and

$$F_p : \mathcal{C} \rightarrow \mathcal{C}_p$$

$$(l, v) \mapsto (l, v^*)$$

**Proposition 4.1** The map $F_p$ is a diffeomorphism.

**Proof.** The map $F_p$ is clearly of class $C^\infty$. It is injective as the vector $v$ is spacelike and $l$ is lightlike. To show that it is surjective, let $(l, w) \in \mathcal{C}_p$ and consider the horocycle $c(s) = p + sw - s^2/(2(p, l))l$ through $p$. We are seeking a vector $v = w - (s_1/(p, l))l$ tangent to the horocycle at $c(s_1)$ and orthogonal to a plane that passes through $p_0 = (1, 0, 0, 0)$. So we require $(p_0, v) = 0$. This gives $s_1 = (p_0, w)/(p, l) / (p_0, l)$ and $v = w - (p_0, w)/(p_0, l)l$. The inverse map $F_p^{-1}(l, w) = (l, w - (p_0, w)/(p_0, l)l)$ is clearly of class $C^\infty$. $\square$
Let \( p \) be a point on an embedded surface \( M \) in \( H^3_+(-1) \) and \( w \in T_pM \). Then as a consequence of Proposition 4.1, if \((l, w) \in C_p\), there is a unique \( v \in S^2_+ \) such that \( w = v^* \).

We have the following geometric characterisations of the singularities of \( P_{(l,v)} \), where “worse” means more degenerate, alternatively, has a higher \( A_c \)-codimension.

**Theorem 4.2** Let \( M \) be an embedded surface in \( H^3_+(-1) \) and \((l, v) \in C\).

1. The projection \( P_{(l,v)} \) is singular at \( p \in M \) if and only if \( v^* \in T_pM \).
2. For \( v \in S^2_0 \) fixed and \( p \in M \), there is a circle of directions \( l \in S^2_+ \subset LC^* \) such that \( v^* \in T_pM \). This circle contains the directions \( \overline{L}^\pm(p) = p \pm e(p) \).
3. The projection \( P_{(l,v)} \) has a singularity of type cusp or worse at \( p \in M \) if and only if \( v^* \in T_pM \) and \( \kappa(v^*) = -\lambda(p, l) \), where \( \lambda(p, l) = \langle e(p), l \rangle / \langle p, l \rangle \). So, for \( l \) fixed, there are at most two directions \( v^* \in T_pM \) for which the singularity of \( P_{(l,v)} \) is of type cusp or worse.
4. The projection \( P_{(l,v)} \) has a singularity of type lips/beaks or worse at \( p \in M \) if and only if \( v^* \) is a principal direction and \( -\lambda(p, l) \) is its associated de Sitter principal curvature. There are two directions \( l \) that satisfy \( \kappa_1 = -\lambda(p, l) \) (or \( \kappa_2 = -\lambda(p, l) \)).
5. The curves \( \kappa_i = \text{constant}, \ i = 1, 2, \) are the loci of points where the two directions in (3) coincide. They foliate the region \(-1 \leq \kappa_i \leq 1, \ i = 1, 2\). (Recall that the curves \( \kappa_i = \pm 1, \ i = 1, 2, \) are part of the horo-parabolic set associated to \( K^+_h \).)
6. The equality \( \kappa(v^*) = -\lambda(p, l) = \pm 1 \) holds if and only if \( l = \overline{L}^\pm(p) \) and \( v^* \) is a horo-asymptotic direction. So the projection \( P_{(l^\pm(p),v)} \) has a singularity of type cusp at \( p \) or worse if and only if \( v^* \) is a horo-asymptotic direction. The singularity is of type lips/beaks or worse if and only if \( p \) is a horo-parabolic point and \( v^* \) is the unique horo-asymptotic direction at \( p \) (which is also a principal direction).
7. Let \( p \) be an umbilic point, \( l \in S^2_+ \) with \( |\kappa_1| < 1 \). Then the projection \( P_{(l,v)} \) has a singularity of type lips/beaks or worse for any \( v \in S^2_0 \) with \( v^* \in T_pM \) and \( l \in S^2_+ \) with \( -\lambda(p, l) = \kappa_1 \). For all directions \( v^* \in T_pM \), except a finite number of them, the singularity is genuinely of type lips/beaks. There are generically 0, 2, 4, 6 directions in \( T_pM \) where the singularity becomes of type 115 and 0, 2, 4, 6, 8 where it becomes of type 43.

**Proof.** The statements in the theorem are of local nature, so we shall take the surface \( M \) in hyperbolic Monge form (H-Monge form, see [19]) at the point in consideration. In fact, by hyperbolic motions, we can suppose that the point of interest is \( p_0 = (1, 0, 0, 0) \) and the surface given locally by

\[
x(x, y) = \left( \sqrt{f(x, y)^2 + x^2 + y^2 + 1}, f(x, y), x, y \right),
\]

with \((x, y)\) in some neighbourhood of the origin. Here \( f \) is a smooth function with \( f(0, 0) = 0 \) and \( f_x(0, 0) = f_y(0, 0) = 0 \). So a unit normal to \( M \) at \( p_0 \) is given by
\( e(0, 0) = (0, 1, 0, 0) \). We shall write the Taylor expansion of \( f \), at the origin, in the form

\[
f(x, y) = a_{20}x^2 + a_{21}xy + a_{22}y^2 + \sum_{i=0}^{3} a_{3i}x^{3-i}y^i + \sum_{i=0}^{4} a_{4i}x^{4-i}y^i + \text{h.o.t.}
\]

Let \( v = (0, v_1, v_2, v_3) \in S^2_+ \). In order to make the contribution of \( \langle p_0, l \rangle \) apparent, we take \( l \) on a sphere in \( LC^* \) with \( l_0 = \text{constant} \). Then \( l_0 = \langle p_0, l \rangle \). (If \( l \in S^2_+ \), then \( \langle p_0, l \rangle = 1 \).) We assume that \( \langle l, v \rangle = 0 \). We have \( v^* = v \) at \( p_0 \) and

\[
\begin{align*}
\partial P_{(l,v)}/\partial x(0,0) &= (0, -v_1v_2, 1 - v_2^2, -v_2v_3), \\
\partial P_{(l,v)}/\partial y(0,0) &= (0, -v_1v_3, -v_2v_3, 1 - v_3^2).
\end{align*}
\]

These two vectors are linearly dependent if and only if \( v_1 = 0 \), if and only if \( v^* \in T_{p_0} M \), which proves (1).

(2) We suppose from now on that \( v_1 = 0 \). Then \( v_2^2 + v_3^2 = 1 \) and \( l = (l_0, l_1, -tv_3, tv_2) \) with \( l_1^2 + l^2 = l_0^2 \). We still denote \( \tilde{L}^+(p) \) the projection of \( p + e(p) \) to the sphere \( l_0 = \text{constant} \). We have \( \tilde{L}^+(p_0) = (l_0, \pm l_1, 0, 0) \), so \( \langle \tilde{L}^+(p_0), v \rangle = 0 \) for any \( v = v^* \in T_{p_0} M \).

(3), (4) and (5) We write \( P_{(l,v)}[i] \) for the \( i \)th coordinate function of \( P_{(l,v)} \). The tangent plane \( \Pi \) of \( HP(v, 0) \cap H^+_2 \) at \( p_0 \) is generated by the two vectors \((0, 1, 0, 0)\) and \((0, 0, -v_3, v_2)\). Let \( \pi : HP(v, 0) \cap H^+_2 (-1) \rightarrow \Pi \) denote the linear projection along the vector \( v \). Consider the composite map

\[
\pi \circ P_{(l,v)} = (0, P_{(l,v)}[2], v_3(P_{(l,v)}[3] - v_2P_{(l,v)}[4]), -v_2(v_3P_{(l,v)}[3] - v_2P_{(l,v)}[4])),
\]

which is \( \mathcal{A} \)-equivalent to the map-germ \( \mathbb{R}^2, 0 \rightarrow \mathbb{R}^2, 0 \) given by

\[
\tilde{P}_{(l,v)} = (P_{(l,v)}[2], v_3P_{(l,v)}[3] - v_2P_{(l,v)}[4]).
\]

As the singularities of \( P_{(l,v)} \) restricted to \( M \) and those of \( \tilde{P}_{(l,v)} \) are \( \mathcal{A} \)-equivalent, we work with the map-germ \( \tilde{P}_{(l,v)} \). We reduce the appropriate \( k \)-jets of \( \tilde{P}_{(l,v)} \) to the form \((x, g(x, y))\) and interpret geometrically the conditions for this germ to be \( \mathcal{A} \)-equivalent to one in Table 1. A calculation shows that

\[
j^2 \tilde{P}_{(l,v)} \sim_\mathcal{A} (x, (2a_0v_2^2 + a_{21}v_2v_3 + a_{22}v_3^2) - l_1)y^2 + ((2a_0v_2 + v_3a_{21})l_0 - v_2l_1)xy.
\]

The singularity of \( P_{(l,v)} \) at \( p_0 \) is of type cusp or worse if and only if the coefficient of \( y^2 \) in the above expression vanishes. This is the case if and only if

\[
2(a_0v_2^2 + a_{21}v_2v_3 + a_{22}v_3^2) = \frac{l_1}{l_0},
\]

which can be written as

\[
\kappa(v^*) = -\frac{\langle e(p_0), l \rangle}{\langle p_0, l \rangle}, \quad (1)
\]
Since $l \in LC^*$, $l_l^2 + l_l^2 + l_l^2 = l_0^2$, so $|l_1/l_0| \leq 1$. (Alternatively, we can choose $p_0, e(p_0), v^*, v^\perp$ as an orthonormal basis of $\mathbb{R}^3$, where $v^\perp$ is a unit orthogonal vector to $v^*$ in $T_{p_0}M$. We have $\langle l, v^* \rangle = 0$, so $l = \langle e(p_0), l \rangle p_0 + \langle e(p_0), l \rangle e(p_0) + \langle v^\perp, l \rangle v^\perp$. But $l \in LC^*$, so $-\langle p_0, l \rangle + \langle e(p_0), l \rangle + \langle v^\perp, l \rangle = 0$, which gives $|\langle e(p_0), l \rangle / \langle p_0, l \rangle| \leq 1$.)

Now, $\kappa(v^*) = \cos^2 \theta \kappa_1 + \sin^2 \theta \kappa_2$, with $\theta$ the angle $v^*$ makes with the principal direction $p_1$ associated to $\kappa_1$. Therefore $\kappa_1 \leq \kappa(v^*) \leq \kappa_2$, so for equation (1) to have a solution (in $v$ or $l$) we need $m = \min(|\kappa_1|, |\kappa_2|) \leq 1$. If $m > |\lambda(p_0, l)|$ where $\lambda(p_0, l) = \langle e(p_0), l \rangle / \langle p_0, l \rangle = -l_1/l_0$, then there are no solutions to $\kappa(v^*) = -\lambda(p_0, l)$. If $m < |\lambda(p_0, l)|$, for any $\lambda$ there are two directions in the tangent space that satisfy the equation $\kappa(v^*) = -\lambda(p_0, l)$. A short calculation shows that the two directions coincide if and only if

$$\begin{align*}
\left(\frac{l_1}{l_0}\right)^2 - 2(a_{22} + a_{20})\frac{l_1}{l_0} + 4a_{20}a_{22} - a_{21}^2 = 0.
\end{align*}$$

This means that $-\lambda(p_0, l)$ is a de Sitter principal curvature, and the direction $v^*$ is the associated principal direction. When this is the case, the coefficient of $xy$ in the expression for the 2-jet of $P_{t,v}$ also vanishes. So the singularity becomes of type lips/beaks or worse.

(6) In the above setting, if $|\lambda(p_0, l)| = 1$, then $\langle v^\perp, l \rangle = 0$. This means that $l = \langle p_0, l \rangle (p_0 \pm e(p_0))$, therefore $l = \pm \tilde{P}(p_0)$.

We know that $\tilde{\kappa}(v^*) = -1 \pm \kappa(v^*)$, so $\kappa(v^*) = \pm 1$ if and only if $\kappa(v^*) = 0$, if and only if $v^*$ is a horo-asymptotic direction.

(7) Follows by analysing the 3-jet of $P_{l,v}$ at an umbilic point. \qed

**Proposition 4.3** The projection $P_{\tilde{P}(p_0),v}$ has a singularity of type swallowtail $(11_5)$ or worse at $p$ if and only if $v^*$ is a horo-asymptotic direction and $p$ is a geodesic inflection on the associated horo-asymptotic direction. The locus of such points form generically a smooth curve on $M$ that we label the horo-flecnodal curve of $M$.

**Proof.** We choose the setting of the proof of Theorem 4.2, take $p = p_0$ and analyse the 3-jet of $P_{\tilde{P}(p_0),v}$. We write this 3-jet in the form $(x, g(x, y))$. Then $p_0$ is a is swallowtail singularity (or worse) of $P_{\tilde{P}(p_0),v}$, if and only if $\partial^2 g / \partial y^2(0, 0) = 0$. Calculations show that this is the case if and only if

$$(1 \pm 2a_{20})v_2^2 \pm 2a_{21}v_2v_3 + (1 \pm 2a_{22})v_3^2 = 0$$

(i.e., $v^* = (0, 0, v_2, v_3)$ is a horo-asymptotic direction) and

$$C(v_2, v_3) = a_{30}v_2^3 + a_{31}v_2^2v_3 + a_{32}v_2v_3^2 + a_{33}v_3^3 = 0$$

where $C$ is the cubic part of $f$. To simplify the calculations, we rotate the axis in the tangent plane and suppose that $(0, 0, 1, 0)$ is a horo-asymptotic direction, so
1 ± 2a_{20} = 0. Then the singularity is of type swallowtail or worse if and only if \( a_{30} = 0 \).

The equation of the horo-asymptotic curves in the parameter space is given by 
\[
\ddot{L}dx^2 + 2\ddot{m}dxdy + \ddot{n}dy^2 = 0,
\]
where \( \ddot{L}, \ddot{m}, \ddot{n} \) are the coefficients of the hyperbolic second fundamental form. Then the horo-asymptotic curve tangent to \( v^* = (0, 0, 1, 0) \) is parametrised by
\[
\gamma(t) = (1 + \frac{1}{2}t^2, \pm \frac{1}{2}t^2, t, -\frac{3a_{30}}{2a_{21}}t^2) + \text{h.o.t.}
\]
The geodesic curvature of this asymptotic curve at \( p_0 \) is \( \frac{3a_{30}}{2a_{21}} \). This vanishes when \( a_{30} = 0 \), equivalently when the singularity of the projection is of type swallowtail or worse.

To show that the horo-flecnodal curve is generically a smooth curve, one can follow the method in [5] (see also [8]) and consider the Monge-Taylor map \( \phi : U \rightarrow J^3(2) \) which associates to \((x, y) \in U\) the 3-jet of \( f \) at \((x, y)\), where \( f \) is the function in the parametrisation of the surface \( \mathbf{x}(U) \) in H-Monge form. The swallowtail singularities form a smooth variety in \( J^3(2) \) and for generic surfaces \( \phi(U) \) intersects this variety transversally. The horo-flecnodal curve is the pre-image of this intersection, so is generically a smooth curve.

We call the image of the critical set of \( P_{(l,v)} \) the contour (or profile) of \( M \). We shall suppose here that it is a smooth curve and restrict to the case where \( l = \tilde{L}^\pm(p_0) \) at some point \( p_0 \in M \). We call the intersection of \( M \) with the 3-dimensional space generated by the vectors \( p_0, v^* \) and \( e(p_0) \) the normal section of \( M \) at \( p_0 \) along \( v^* \).

Koenderink showed in [30] that for embedded surfaces in \( \mathbb{R}^3 \), the Gaussian curvature of the surface at a given point is the product of the curvature of the contour with the curvature of the normal section in the direction of projection. We have the following result for the projections \( P_{(L^\pm(p_0),v)} \), where the curvature of a curve in \( H^3_\pm(-1) \) is as given in §3.

**Theorem 4.4** (Koenderink type theorem) Let \( \kappa_c \) be the curvature of the contour and \( \kappa_n \) the curvature of the normal section. If the point on the surface is also on the plane of projection (alternatively, if \( v \in T_pM \)), then
\[
K^\pm_h = (\kappa_c + 1)(\kappa_n + 1).
\]
Otherwise, the left hand side of the above equality depends on \( (v^*, p) \).

**Proof.** We take, without loss of generality, the surface in the H-Monge form as in the proof of Theorem 4.2, \( v = v^* = (0, 0, 0, 1) \) and \( l = (1, \pm 1, 0, 0) \) at \( p_0 = (1, 0, 0, 0) \). We assume that the singularity of the projection is a fold at \( p_0 \), so \( 2a_{22} \pm 1 \neq 0 \). Then the 2-jet of the profile is given by
\[
(1 + \frac{1}{2}t^2, \frac{(4a_{20}a_{22} - 2a_{20} - a_{21}^2)}{2(2a_{22} - 1)}t^2, t, 0).
\]
Following the formula in §3, its curvature at $p_0$ is given by 

$$
\kappa_c = \frac{4a_{20}a_{22} - a_{21}^2 + 2a_{20}}{2a_{22} \mp 1}.
$$

The normal section of the surface along $v$ is given by $(\sqrt{f(0, y)^2 + y^2 + 1}, f(0, y), 0, y)$ and its curvature at $p_0$ is given by $\kappa_n = 2a_{22}$. Given the fact that the hyperbolic curvature of the surface at $p_0$ is $K_h^\pm = 4a_{20}a_{22} - a_{21}^2 \mp 2a_{20} \mp 2a_{22} + 1$, it follows that 

$$
\kappa_c = \frac{K_h^\pm}{\kappa_n + 1} - 1,
$$
equivalently,

$$
K_h^\pm = (\kappa_c + 1)(\kappa_n + 1).
$$

We now show that the above formula does not hold if $p_0$ does not belong to the plane of projection. Let $\lambda \in \mathbb{R}$ and consider the map 

$$
hc : \ H \mathcal{P}(v, 0) \cap H^3_+(v, -1) \rightarrow H \mathcal{P}(v, \lambda) \cap H^3_+(v, -1)
$$

that takes a point on the plane determined by $v \in S^2_0$ to a point on another parallel plane along the horocycles $(l, v) \in \mathcal{C}$. It is not difficult to show that the curvature of a curve $\gamma(t) \subset H \mathcal{P}(v, 0) \cap H^3_+(v, -1)$ is distinct from that of $hc(\gamma(t)) \subset H \mathcal{P}(v, \lambda) \cap H^3_+(v, -1)$ when $\lambda \neq 0$. So if we project to $H \mathcal{P}(v, \lambda) \cap H^3_+(v, -1)$ instead, the left hand side of the above equality remains the same while the value of $\kappa_c$ changes as $\lambda$ varies. So the equality does not hold in this case.

**5 Duality**

We prove in this section duality result similar to those in [34] for central projections of surfaces in $\mathbb{R}P^3$ and to those in [9] for orthogonal projections of surfaces in $\mathbb{R}^3$.

Let $M$ be an embedded surface in $H^3_+(v, -1)$. We shall use the duality concepts in [13, 14, 25], see §6 for details. In [24] is introduced the notion of a horocyclic surface which is defined to be a one-parameter family of horocylces in $H^3_+(v, -1)$. We denote by $A_2^{h-par}$ the horocyclic surface in $H^3_+(v, -1)$ swept out by the horocycles in $H^3_+(v, -1)$ passing through a horo-parabolic point of $M$ and with tangent direction there the unique horo-asymptotic direction. We also denote by $(A_2^{h-par})^{(1,*)}$ the $\Delta_1$-dual of $A_2^{h-par}$.

A bi-tangent horosphere of $M$ is a horosphere $HS^3(l, c)$ tangent to $M$ at two distinct points. If there exist points $p_1, p_2 \in M$ such that $\Lambda^\pm(p_1) = \Lambda^\pm(p_2)$ and $\langle p_1, \Lambda^\pm(p_1)\rangle = \langle p_2, \Lambda^\pm(p_2)\rangle$, then we have the bi-tangent horosphere $HS^3(\Lambda^\pm(p_1), \langle p_1, \Lambda^\pm(p_1)\rangle)$ at $p_1$ and $p_2$. In this case, there exists a unique horocycle in $HS^3(\langle p_1, \Lambda^\pm(p_1)\rangle)$
passing through $p_1$ and $p_2$. We call such horocycle a \textit{bi-tangent horocycle to $M$ relative to $\mathbb{L}^\pm(p_1) = \mathbb{L}^\pm(p_2)$}. We denote by $A_1^h||A_2^h$ the horocyclic surface swept out by the bi-tangent horocycles to $M$ relative to the lightcone normal at points on the bi-tangent locus of horospheres to $M$.

\textbf{Theorem 5.1} Let $M$ be an embedded surface in $H^3_+(-1)$ and $M^{(2,*)}$ its $\Delta_2$-dual. Then,

1. The $\Delta_2$-dual of the surface $A_2^{h-par}$ is the cuspidal edge of $M^{(2,*)}$.
2. The $\Delta_2$-dual of the surface $A_1^h||A_2^h$ is the self-intersection curve of $M^{(2,*)}$.
3. The $\Delta_3$-dual of the surface $(A_2^{h-par})^{(1,*)}$ is the cuspidal edge of $-M^{(2,*)}$, where $-M^{(2,*)}$ denotes the antipodal surface of $M^{(2,*)}$.

\textbf{Proof.} We consider a local parametrisation $\mathbf{x}: U \rightarrow H^3_+(-1)$ of $M$ (i.e., $M = \mathbf{x}(U)$). In this case $M^{(2,*)} = \mathbb{L}^\pm(U)$.

1. We suppose that the horo-parabolic set $K^+_h = 0$ is a regular curve. This property holds for generic embeddings of surface $M$ in $H^3_+(-1)$. Let $p(t)$, $t \in I$, be a parametrisation of the horo-parabolic set of $M$ and $u(t)$ the unique unit horo-asymptotic direction at $p(t)$. There exists a curve $\gamma: I \rightarrow U$ such that $\mathbf{x}(\gamma(t)) = p(t)$ and $u(t) \in T_{\gamma(t)}M$. Then we have $e(t) = \mathbf{E}(\gamma(t))$, so that $\mathbb{L}^\pm(\gamma(t)) = p(t) \pm e(t)$. Since $p(t) = \mathbf{x}(\gamma(t))$ is a parametrisation of $K^+_h(0)$ which is the singular locus of $\mathbb{L}^\pm$, $\mathbb{L}^\pm(\gamma(t)) = p(t) \pm e(t)$ is the cuspidal edge of $M^{(2,*)} = \mathbb{L}^\pm(U)$.

The horocyclic surface $A_2^{h-par}$ is parametrised by

$$y(s, t) = p(t) + su(t) + \frac{s^2}{2}(p(t) \pm e(t)).$$

We have

$$\frac{\partial y}{\partial s}(s, t) = u(t) + s(p(t) \pm e(t)) \quad \text{and} \quad \frac{\partial y}{\partial t}(s, t) = p'(t) + su'(t) + \frac{s^2}{2}(p'(t) \pm e'(t)).$$

Since $u(t) \in T_{\gamma(t)}M$ and $\mathbb{L}^\pm(\gamma(t)) = p(t) \pm e(t)$ is a lightlike normal to $M$, we have

$$\left\langle \frac{\partial y}{\partial s}(s, t), \mathbb{L}(\gamma(t)) \right\rangle = 0.$$

We remark that $p'(t) \in T_{\gamma(t)}M$ and $\langle p'(t) \pm e'(t), p(t) \pm e(t) \rangle = 0$. Therefore, we have

$$\left\langle \frac{\partial y}{\partial t}(s, t), p(t) \pm e(t) \right\rangle = s\langle u'(t), p(t) \pm e(t) \rangle.$$

Taking the derivative of the relation $\langle p(t) \pm e(t), u(t) \rangle = 0$, we have

$$\langle d\mathbb{L}^\pm(\gamma(t))p'(t), u(t) \rangle = \langle (\mathbb{L}^\pm)'(\gamma(t)), u(t) \rangle = -\langle p(t) \pm e(t), u'(t) \rangle.$$
The fact that \( p(t) \) is the parametrisation of horo-parabolic set means that the image of \( d\mathbb{L}^\pm(\gamma(t)) \) is one dimensional, so that there exists \( \lambda \in \mathbb{R} \) such that
\[
d\mathbb{L}^\pm(\gamma(t))p'(t) = \lambda d\mathbb{L}^\pm(\gamma(t))u(t).
\]
Since \( u(t) \) is the unique asymptotic direction, we have
\[
\langle d\mathbb{L}^\pm(\gamma(t))p'(t), u(t) \rangle = \lambda \langle d\mathbb{L}^\pm(\gamma(t))u(t), u(t) \rangle = 0.
\]
It follows that
\[
\left\langle \frac{\partial y}{\partial t}(s, t), \mathbb{L}^\pm(\gamma(t)) \right\rangle = 0.
\]
So the lightlike normal to the horocyclic surface \( A_2^{h_{\text{par}}} \) is constant along each horocycle. (This means that the image of the lightcone normal to \( A_2^{h_{\text{par}}} \) is a curve in \( \mathcal{L}^\ast \), which implies that \( A_2^{h_{\text{par}}} \) is a horo-flat horocyclic surface in \( H^3_+(-1) \); see [24].) Moreover, we have \( \langle y(s, t), \mathbb{L}^\pm(\gamma(t)) \rangle = -1 \). Therefore \( y(s, t) \) and \( \mathbb{L}^\pm(\gamma(t)) \) are \( \Delta_\gamma \)-dual.

(2) Suppose that there exists a bi-tangent horocycle to \( M \) at two points \( p_1 \) and \( p_2 \) on \( M \). The surface \( A_1^h||A_1^h \) is then a horocyclic surface generated by horocycles along a curve \( C_1 \) on \( M \) through \( p_1 \) (or a curve \( C_2 \) through \( p_2 \)). The lightlike normals \( \mathbb{L}^\pm \) of \( M \) along \( C_1 \) and \( C_2 \) coincide. Let \( q(t) \) be a local parametrisation of the curve \( C_1 \) and \( v(t) \) be the unit tangent direction to the horocycle in \( A_1^h||A_1^h \) through \( q(t) \). We also denote by \( e(t) \) the de Sitter normal to \( M \) along \( C_1 \), so that the lightcone normal to \( M \) along \( C_1 \) is given by \( \mathbb{L}^\pm(t) = q(t)\pm e(t) \). Then a local parametrisation of \( A_1^h||A_1^h \) is given by
\[
z(s, t) = q(t) + sv(t) + \frac{s^2}{2}(q(t) \pm e(t)).
\]
It follows that
\[
\frac{\partial z}{\partial s}(s, t) = v(t) + s(q(t) \pm e(t)) \quad \text{and} \quad \frac{\partial z}{\partial t}(s, t) = q'(t) + sv'(t) + \frac{s^2}{2}(q'(t) \pm e'(t)).
\]
By the same arguments in case (1), we have
\[
\left\langle \frac{\partial z}{\partial s}(s, t), q(t) \pm e(t) \right\rangle = 0 \quad \text{and} \quad \left\langle \frac{\partial z}{\partial t}(s, t), q(t) \pm e(t) \right\rangle = s(v'(t), q(t) \pm e(t)).
\]
Since \( C_1 \) and \( C_2 \) are disjoint, \( C_2 \) can be parametrised by \( q_2(t) = z(s(t), t) \) for some non-zero smooth function \( s(t) \). On \( C_2 \), we have
\[
0 = \left\langle \frac{\partial z}{\partial t}(s(t), t), q(t) \pm e(t) \right\rangle = s(t)(v'(t), q(t) \pm e(t)).
\]
Since \( s(t) \neq 0 \), we have \( \langle v'(t), q(t) \pm e(t) \rangle = 0 \), so that
\[
\left\langle \frac{\partial z}{\partial t}(s, t), q(t) \pm e(t) \right\rangle = 0.
\]
So the lightlike normal to the horocyclic surface $A_2^h||A_2^h$ is constant along each horocycle. (This means that the image of the lightcone normal to $A_2^h||A_2^h$ is a curve in $LC^*$, which implies that $A_2^h||A_2^h$ is a horo-flat horocyclic surface in $H^3_+(-1)$; see [24].) Moreover, we have $\langle z(t,s), L_\pm(t) \rangle = -1$. This means that $z(s,t)$ and $L_\pm(t)$ are $\Delta_2$-dual.

The maps $q(t) = z(t,0)$ and $z(t,s(t))$ are parametrisations of $C_1$ and $C_2$ respectively. Therefore, $L_\pm(t)$ is the common lightcone normal to $M$ at $q(t)$ and $z(t,s(t))$, which is the self intersection curve of $M^{(2,*)}$.

(3) We use here the notation in case (1) and define the contact diffeomorphism $\Psi_{31} : \Delta_3 \rightarrow \Delta_1$ by $\Psi_{31}(v,w) = (v - w, -w)$. We also define the mapping

$$w(s,t) = \pm e(t) - su(t) - \frac{s^2}{2}(p(t) \pm e(t)).$$

One can easily show that $w(s,t) \in S_1^\ast$ and $\langle p(t) \pm e(t), w(s,t) \rangle = 1$. By almost the same calculations as those in case (1), we can show that

$$\left\langle \frac{\partial w}{\partial s}(s,t), q(t) \pm e(t) \right\rangle = 0 \quad \text{and} \quad \left\langle \frac{\partial w}{\partial t}(s,t), q(t) \pm e(t) \right\rangle = 0.$$

This means that $L_\pm(\gamma(t)) = p(t) \pm e(t)$ and $w(s,t)$ are $\Delta_3$-dual. We also have

$$\Psi_{31}(L_\pm(\gamma(t)), w(s,t)) = (y(s,t), -w(s,t)).$$

Therefore $y(s,t)$ is the $\Delta_1$-dual of $-w(s,t)$. Since $y(s,t)$ gives a local parametrisation of $A_2^{h-par}$, $-w(s,t)$ is a local parametrisation of $(A_2^{h-par})^{(1,*)}$. By definition, $\Delta_3$ is invariant under the antipodal action on $\mathbb{R}^4$, so $(A_2^{h-par})^{(1,*)}$ is the $\Delta_3$-dual of $-L_\pm(\gamma(t))$ which is the cuspidaledge of $-M^{(2,*)}$. 

There are Euclidean analogues in [9] of the results in [34] (see also [3, 4, 7] for related results). Given an embedded surface $M$ in the Euclidean space $\mathbb{R}^3$ the family of height functions on $M$ is given by

$$H_E : M \times S^2 \rightarrow \mathbb{R} \times S^2$$

$$(q,v) \mapsto q.v$$

and the family of orthogonal projections is given by

$$P_E : M \times S^2 \rightarrow TS^2$$

$$(q,v) \mapsto (q, q - (q.v)v)$$

where $S^2$ denotes the unit sphere and “.” the scalar product in $\mathbb{R}^3$. The local bifurcation set $\text{Bif}(H_E)$ of $H_E$ (resp. $\text{Bif}(P_E)$ of $P_E$) is the set of $u \in S^2$ for which there exist $p \in M$ such that $H_E(-,u)$ (resp. $P_E(-,u)$) has a non-stable singularity at $p$. The $A_2$-stratum of $\text{Bif}(H_E)$ is the set of unit normals at the parabolic points of
The lips/beaks stratum of $Bif(P_E)$ is the set of unit asymptotic directions at the parabolic points of $M$. It is shown in [9] that the $A_2$-stratum of $Bif(H_E)$ is dual to the lips/beaks stratum of $Bif(P_E)$. The duality in [9] refers to the double Legendrian fibration $S^2 \xrightarrow{\pi_1} \Delta \xrightarrow{\pi_2} S^2$, where $\Delta = \{(u, v) \in S^2 \times S^2 \mid u \cdot v = 0\}$. The contact structure on $\Delta$ is given by the 1-form $\theta = v.du|_\Delta$.

We seek an analogous duality result for the family of projections along horocycles. The family of lightcone height functions on $M$ is generically smooth. Consider the projections $\pi : M \times S^2_+ \rightarrow \mathbb{R} \times S^2_+$ and $\pi_2 : S^2_+ \rightarrow S^2_0$ are Legendrian fibrations. Therefore, given a Legendrian curve $i : L \rightarrow C$, $\pi_1(i(L))$ is dual to $\pi_2(i(L))$ and vice-versa. We call this duality $C$-duality. (See §6 for more details on Legendrian duality.)

Suppose that the horo-parabolic set of $M \in H^3_+(-1)$ is smooth (which is generically the case) and is parametrised locally by $p(t), t \in I$. Let $u(t)$ be the unique horo-asymptotic direction at $p(t)$ and $(\tilde{L}^+(p(t)), v(t)) = F_{p(t)}^{-1}(\tilde{L}^+(p(t)), u(t))$, with $F_p$ the map in Proposition 4.1. We have the following consequence of the $C$-duality.

**Proposition 5.2** The curve $L = \{(\tilde{L}^+(p(t)), v(t)), t \in I\}$ is a Legendrian curve in $C$. Therefore $\pi_1(L)$ and $\pi_2(L)$ are $C$-dual curves. That is, the $A_2$-stratum of the bifurcation set of the family of lightcone height functions is $C$-dual to the set of unit horo-asymptotic directions at horo-parabolic points transported along horocycles to $S^2_0$.

The set of unit horo-asymptotic directions at horo-parabolic points transported along horocycles to $S^2_0$ is not of course the lips/beaks stratum of the bifurcation set of the family of projections along horocycles. The lips/beaks stratum of this family is generically a 2-dimensional surface in $C$. However, the curve $L = \{(\tilde{L}^+(p(t)), v(t)), t \in I\}$ is special on this stratum. To show this, let

$$S(4_2) = \{(p, (l, v)) \in M \times C \mid P_{(l,v)} \text{ has a singularity at } p \text{ of type lips/beaks}\},$$

The surface $S(4_2)$ is generically smooth. Consider the projections $\pi_1 : S(4_2) \subset M \times C \rightarrow M$ and $\pi_2 : S(4_2) \subset M \times C \rightarrow C$.

**Proposition 5.3** Suppose that $p$ is not an umbilic point. Then the projection $\pi_1$ is singular if and only if $p$ is a horo-parabolic point, $l = \tilde{L}^+(p)$ and $v^\ast$ is the unique horo-asymptotic direction at $p$. Therefore $L = \{(\tilde{L}^+(p(t)), v(t)), t \in I\} = \pi_2(\Sigma(\pi_1))$. 

17
Proof. The proof follows by direct calculations using the H-Monge form setting. □

6 Appendix

We require some properties of contact manifolds and Legendrian submanifolds for the duality results in this paper (for more details see for example [2]). Let \( N \) be a \((2n+1)\)-dimensional smooth manifold and \( K \) be a field of tangent hyperplanes on \( N \). Such a field is locally defined by a 1-form \( \alpha \). The tangent hyperplane field \( K \) is said to be \textit{non-degenerate} if \( \alpha \wedge (d\alpha)^n \neq 0 \) at any point on \( N \). The pair \((N, K)\) is a \textit{contact manifold} if \( K \) is a non-degenerate hyperplane field. In this case \( K \) is called a \textit{contact structure} and \( \alpha \) a \textit{contact form}.

A submanifold \( i : L \subset N \) of a contact manifold \((N, K)\) is said to be \textit{Legendrian} if \( \dim L = n \) and \( di_x(T_xL) \subset K_{i(x)} \) at any \( x \in L \). A smooth fibre bundle \( \pi : E \to M \) is called a \textit{Legendrian fibration} if its total space \( E \) is furnished with a contact structure and the fibres of \( \pi \) are Legendrian submanifolds. Let \( \pi : E \to M \) be a Legendrian fibration. For a Legendrian submanifold \( i : L \subset E, \pi \circ i : L \to M \) is called a \textit{Legendrian map}. The image of the Legendrian map \( \pi \circ i \) is called a \textit{wavefront set} of \( i \) and is denoted by \( W(i) \).

The duality concepts we use in this paper are those introduced in [13, 14, 25], where five Legendrian double fibrations are considered on the subsets \( \Delta_i, i = 1, \ldots, 5 \) below, of the product of two of the pseudo spheres \( H^n(-1), S^n_1 \) and \( LC^* \). The geometric ideas behind the choice of the subsets \( \Delta_i \) and the Legendrian double fibrations are as follows (for more details see [13, 14, 25]).

To any hypersurface \( \mathbf{x} : U \to H^n(-1) \) is associated the de Sitter Gauss map \( \mathbf{E} : U \to S^n_1 \). It is easy to show that the pair \((\mathbf{x}, \mathbf{E}) : U \to H^n(-1) \times S^n_1 \) is a Legendrian embedding into the set \( \Delta_1 = \{(v, w) \in H^n(-1) \times S^n_1 \mid \langle v, w \rangle = 0\} \). (The contact structure on \( \Delta_1 \) is given below.) This means that \( M = \mathbf{x}(U) \) and \( M^{(1,*)} = \mathbf{E}(U) \) are dual. We call this duality the \( \Delta_1\)-\textit{duality}. This is a direct analogue of the spherical duality in the Euclidean space.

Consider now the lightcone Gauss map \( \mathbb{L}^\pm : U \to H^n(-1) \times LC^* \) which satisfies \( \langle \mathbf{x}(u), \mathbb{L}^\pm(u) \rangle = -1 \). The pair \((\mathbf{x}, \mathbb{L}^\pm) : U \to H^n(-1) \times LC^* \) determines a Legendrian embedding into the set \( \Delta_2 = \{(v, w) \in H^n(-1) \times LC^* \mid \langle v, w \rangle = -1\} \), so \( M = \mathbf{x}(U) \) and \( M^{(2,*)} = \mathbb{L}^\pm(U) \) are dual. We call this duality the \( \Delta_2\)-\textit{duality}.

Similarly, we have \( \langle \mathbf{E}(u) \pm \mathbf{x}(u), \mathbf{E}(u) \rangle = 1 \) and \( \langle \mathbb{L}^+(u), \mathbb{L}^-(u) \rangle = -2 \) and these lead to the concepts of \( \Delta_3\)-\textit{duality} and \( \Delta_4\)-\textit{duality} respectively.

For spacelike hypersurfaces embedded in one of the pseudo-spheres in the Minkowski space (i.e. surfaces whose tangent spaces at all points are spacelike), we need to consider only the above four \( \Delta_i\)-dualities, \( i = 1, \ldots, 4 \). However, if we consider timelike hypersurfaces in \( S^n_1 \), (i.e. surfaces whose tangent spaces at all points are timelike) we need the concept of \( \Delta_5\)-\textit{duality} below which is also a direct analogue to the spherical
duality in the Euclidean space. To summarise, we have the following five Legendrian double fibrations.

(1) (a) \( H^n(-1) \times S^n_1 \supset \Delta_1 = \{(v, w) \mid \langle v, w \rangle = 0\}, \)
    (b) \( \pi_{11} : \Delta_1 \rightarrow H^n(-1), \quad \pi_{12} : \Delta_1 \rightarrow S^n_1, \)
    (c) \( \theta_{11} = \langle dv, w \rangle|_{\Delta_1}, \quad \theta_{12} = \langle v, dw \rangle|_{\Delta_1}. \)

(2) (a) \( H^n(-1) \times LC^* \supset \Delta_2 = \{(v, w) \mid \langle v, w \rangle = -1 \}, \)
    (b) \( \pi_{21} : \Delta_2 \rightarrow H^n(-1), \pi_{22} : \Delta_2 \rightarrow LC^*, \)
    (c) \( \theta_{21} = \langle dv, w \rangle|_{\Delta_2}, \quad \theta_{22} = \langle v, dw \rangle|_{\Delta_2}. \)

(3) (a) \( LC^* \times S^n_1 \supset \Delta_3 = \{(v, w) \mid \langle v, w \rangle = 1 \}, \)
    (b) \( \pi_{31} : \Delta_3 \rightarrow LC^*, \pi_{32} : \Delta_3 \rightarrow S^n_1, \)
    (c) \( \theta_{31} = \langle dv, w \rangle|_{\Delta_3}, \quad \theta_{32} = \langle v, dw \rangle|_{\Delta_3}. \)

(4) (a) \( LC^* \times LC^* \supset \Delta_4 = \{(v, w) \mid \langle v, w \rangle = -2 \}, \)
    (b) \( \pi_{41} : \Delta_4 \rightarrow LC^*, \pi_{42} : \Delta_4 \rightarrow LC^*, \)
    (c) \( \theta_{41} = \langle dv, w \rangle|_{\Delta_4}, \quad \theta_{42} = \langle v, dw \rangle|_{\Delta_4}. \)

(5) (a) \( S^n_1 \times S^n_1 \supset \Delta_5 = \{(v, w) \mid \langle v, w \rangle = 0\}, \)
    (b) \( \pi_{51} : \Delta_5 \rightarrow S^n_1, \pi_{52} : \Delta_5 \rightarrow S^n_1, \)
    (c) \( \theta_{51} = \langle dv, w \rangle|_{\Delta_5}, \quad \theta_{52} = \langle v, dw \rangle|_{\Delta_5}. \)

Above, \( \pi_{i1}(v, w) = v \) and \( \pi_{i2}(v, w) = w \) for \( i = 1, \ldots, 5, \langle dv, w \rangle = -w_0 dv_0 + \sum_{i=1}^n w_i dv_i \) and \( \langle v, dw \rangle = -v_0 dw_0 + \sum_{i=1}^n v_i dw_i \). The 1-forms \( \theta_{i1}^{-1} \) and \( \theta_{i2}^{-1} \), \( i = 1, \ldots, 5 \), define the same tangent hyperplane field over \( \Delta_i \) which is denoted by \( K_i \).

We have the following duality theorem on the above spaces.

**Theorem 6.1** ([13, 14, 25]) The pairs \((\Delta_i, K_i), i = 1, \ldots, 5,\) are contact manifolds and \(\pi_{i1}\) and \(\pi_{i2}\) are Legendrian fibrations.

We have the following general remarks, some of which follow from the discussion proceeding Theorem 6.1.

**Remark 6.2** 1. Given a Legendrian submanifold \( i : L \rightarrow \Delta_i, i = 1, \ldots, 5, \) Theorem 6.1 states that \( \pi_{i1}(i(L)) \) is the \(\Delta_i\)-dual of \( \pi_{i2}(i(L)) \) and vice-versa.

2. We have the following geometric properties for a Legendrian submanifold \( L \subset \Delta_i, i = 1, \ldots, 5. \) Take the case \( i = 1. \) If \( \pi_{11}(i(L)) \) is smooth at a point \( \pi_{11}(i(u)) \), then \( \pi_{12}(i(u)) \) is the normal vector to the hypersurface \( \pi_{11}(i(L)) \subset H^n_+(-1) \) at \( \pi_{11}(i(u)) \). Conversely, if \( \pi_{12}(i(L)) \) is smooth at a point \( \pi_{12}(i(u)) \), then \( \pi_{11}(i(u)) \) is the normal vector to the hypersurface \( \pi_{12}(i(L)) \subset S^n_1. \) The same holds for the \(\Delta_i\)-dualities, \( i = 2, \ldots, 5, \) where we take the normal to a hypersurface \( M \subset LC^* \) at \( p \in M \) as the direction given by the intersection of the normal plane to \( T_p M \) in \( \mathbb{R}^{n+1}_1 \) with \( T_p LC^* \).

3. Since the normal of a hypersurface in \( H^n(-1) \) is always spacelike, we have no good duality relationship in \( H^n(-1) \times H^n(-1). \)
Acknowledgement. The results in this paper were established during the visit of FT to Hokkaido University in October 2007. The visit was supported by a Royal Society International Outgoing Short Visit grant 2007/R2. We would like to thank the Royal Society for their support.
