(Received 7 March 2017; accepted 30 April 2017; published online 11 May 2017)

Here, we present a thermoelectric phase diagram for the SrTi1−xNb,O3 (0.05 ≤ x ≤ 1) solid solution system, which we derived from the characterization of epitaxial films. We observed two thermoelectric phase boundaries in the system, which originate from the step-like decrease in carrier effective mass at x ≈ 0.3 and from a local minimum in carrier relaxation time at x ≈ 0.5. The origins of these phase boundaries are considered to be related to isovalent/heterovalent B-site substitution: parabolic Ti 3d orbitals dominate electron conduction for compositions with x < 0.3, whereas the Nb 4d orbital dominates when x > 0.3. At x ≈ 0.5, a tetragonal distortion of the lattice, in which the B-site is composed of Ti4+ and Nb4+ ions, leads to the formation of tail-like impurity bands, which maximizes the electron scattering. These results provide a foundation for further research into improving the thermoelectric performance of SrTi1−x,Nb,O3. Published by AIP Publishing.

I. INTRODUCTION

Thermoelectric energy conversion, in which waste heat is transformed into electricity by the Seebeck effect, is attracting significant research attention as a potential energy harvesting technology.1 Generally, the performance of thermoelectric materials is evaluated in terms of a dimensionless figure of merit, ZT = S2σT/K, where ZT is the figure of merit, S is the thermopower (Seebeck coefficient), σ is the electrical conductivity, T is the temperature, and K is the thermal conductivity. Although the ZT values of several commercialized thermoelectric materials such as Bi2Te3 (ZT ≈ 1@600 K) and PbTe (ZT ≈ 0.8@600 K) are roughly 1,2 these heavy metal–based materials present environmental risks due to the toxicity of their constituent elements and their chemical and thermal instability. Recently, transition metal oxides (TMOs) including Na2CoO2 (x ≈ 0.75),3 Ca2CoO4,[4] and SrTiO3[5–7] have drawn a high volume of research as high-temperature thermoelectric power generation materials: this group of materials is considered to be particularly suitable for these applications due to their chemical and thermal robustness, as well as the comparably low environmental risk.8

Among the available TMOs, electron-doped SrTiO3 has been one of the most extensively studied materials for thermoelectric applications.9 In 2001, Okuda et al.5 synthesized Sr1−xLa,xTiO3 (0 ≤ x ≤ 0.1) single crystals by the floating-zone method and reported that they yielded a large power factor (S2σ) of 2.8–3.6 mW m−1 K−2 at room temperature. After this, Ohta et al. reported the carrier transport properties of Nb- and La-doped SrTiO3 single crystals (carrier concentration, n ≈ 1020 cm−3) at high temperatures (~1000 K) to clarify the intrinsic thermoelectric properties of these materials.6 Furthermore, the experimental discovery of unusually large thermopower outputs from superlattices and two-dimensional electron gases in SrTiO3[9–11] spurred substantial research efforts into SrTiO3 superlattices12 and heterostructures[13] for thermoelectric applications; for example, a superlattice composed of 1 unit cell (uc) SrTi0.8Nb0.2O3 and 10 uc SrTiO3 exhibited giant thermopower, most likely due to an electron confinement effect. Although electron confinement is strongly correlated with the electronic structure,14 a full understanding of the fundamental electronic phase behavior of the SrTi1−x,Nb,O3 solid solution system has not yet been developed.

In this study, we clarify the thermoelectric phase diagram for the full range of the SrTiO3–SrNbO3 solid solution system (hereafter referred to as the SrTi1−,Nb,O3 ss). Although high-quality single crystals of SrTi1−x,Nb,O3 species with x > 0.1 are not available due to the low solubility limit of Nb in the lattice,15 epitaxial films of these material compositions can be fabricated by pulsed laser deposition (PLD).16 As summarized in Fig. 1, pure SrTiO3 (space group Pm3m, cubic perovskite structure, a = 3.905 Å) is an insulator with a bandgap of 3.2 eV, in which the bottom of the conduction band is composed of triply degenerate, empty Ti 3d-t2g orbitals, while the top of the valence band is composed of fully occupied O 2p orbitals.17 The valence state of Ti ions in crystalline SrTiO3 is 4+ (Ti 3d0). On the other hand, pure SrNbO3 (space group Pm3m, cubic perovskite structure, a = 4.023 Å) is a metallic conductor, in which the valence state of the Nb ion is 4+ (Nb 4d1). In between SrTiO3 and SrNbO3 in the SrTi1−,Nb,O3 ss, there are two possible types of valence state change in the Ti and Nb ions, as shown in Figs. 1(b) and 1(c): in the case of isovalent substitution [Fig. 1(b)], mole fraction of Ti4+ proportionally

Figure 1. Schematic crystal structure and possible valence state changes in the SrTiO$_3$–SrNbO$_3$ solid solution system. (a) Schematic crystal structure. Pure SrTiO$_3$ is an insulator with bandgap of 3.2 eV, in which the valence state of the Ti ions (blue, TiO$_6$) is $4^+$ (Ti 3d$^0$). On the other hand, pure SrNbO$_3$ is a metal, in which the valence state of the Nb ions (red, NbO$_6$) is $4^+$ (Nb 4d$^4$). (b)–(c) Possible valence state changes of Ti and Nb ions in the SrTiO$_3$–SrNbO$_3$ solid solution system: (b) isovalent substitution, where Ti$^{4+}$ is substituted by Nb$^{4+}$; (c) heterovalent substitution, where two Ti$^{4+}$/Nb$^{4+}$ ions are substituted by adjacent Ti$^{4+}$/Nb$^{5+}$ ions.

II. EXPERIMENTS

Approximately 100 nm thick SrTi$_{1-x}$Nb$_x$O$_3$ ($x = 0.05, 0.1, 0.2, 0.3, 0.4, 0.5, 0.55, 0.6, 0.7, 0.8, 0.9, and 1.0$) epitaxial films were fabricated by PLD using dense ceramic disks of an SrTiO$_3$–SrNbO$_3$ mixture. We selected insulating (001) LaAlO$_3$ (pseudo-cubic perovskite, $a = 3.79$ Å) as the substrate. Growth conditions were precisely controlled, with a substrate temperature of 850 °C, oxygen pressure of $\sim 10^{-4}$ Pa, laser fluence of 0.5–1 J cm$^{-2}$ pulse$^{-1}$, yielding a growth rate of 0.3 pm pulse$^{-1}$. Details of the PLD growth process of SrTi$_{1-x}$Nb$_x$O$_3$ films developed by our group have been published elsewhere.$^7,20,21$

Crystallographic analyses of the resultant films were performed by X-ray diffraction (XRD, Cu K$_\alpha_1$, ATX-G, Rigaku) and scanning transmission electron microscopy (STEM). TEM samples were fabricated using a cryo ion slicer (IB-09060CIS, JEOL). The thin film was observed using scanning transmission electron microscope (STEM) (JEM-ARM200CF, JEOL Co. Ltd) operated at 200 keV. High-angle annular dark-field (HAADF) images were taken with the detection angle of 68–280 mrad. The electron energy loss spectra (EELS) were acquired in STEM mode by a Gatan Enfinium spectrometer (Gatan Inc.) with the energy resolution of 1 eV.

$\sigma$, carrier concentration ($n$), and Hall mobility ($\mu_{\text{Hall}}$) were measured at room temperature by a conventional d.c. four-probe method, using an In–Ga alloy electrode with van der Pauw geometry. $S$ was measured at room temperature by creating a temperature gradient ($\Delta T$) of $\sim 4$ K across the film using two Peltier devices (while using two small thermocouples to monitor the actual temperatures of each end of the SrTi$_{1-x}$Nb$_x$O$_3$ films). The thermo-electromotive force ($\Delta V$) and $\Delta T$ were measured simultaneously, and $S$-values were obtained from the slope of the $\Delta V$–$\Delta T$ plots.

Band structures for SrTi$_{1-x}$Nb$_x$O$_3$ ($x = 0.0, 0.25, 0.5, 0.75,$ and 1) were calculated based on the projector augmented-wave (PAW) method,$^{22}$ as implemented using VASP code.$^{23}$ For these calculations, we adopted Heyd-Scuseria-Ernzerhof (HSE) hybrid functionals,$^{24}$ and a plane-wave cutoff energy of 550 eV and a $6 \times 6 \times 6$ $k$-point mesh for cubic-perovskite
were employed in the total-energy evaluation and geometry optimization for the unit cells of SrTiO$_3$ and SrNbO$_3$, while special quasi-random structures (SQSs) were used in the case of SrTi$_{1-x}$Nb$_x$O$_3$ ($x = 0.25$, $0.5$, and $0.75$). The SQSs with eight Sr or Ti sites were constructed by optimizing the correlation functions of seven types of independent pairs using the CLUPAN code.\textsuperscript{25}

III. RESULTS AND DISCUSSION

Figure 2(a) summarizes the X-ray reciprocal space mappings (RSMs) around the (103) diffraction spot of LaAlO$_3$ (overlaid). Intense diffraction spots from (103) SrTi$_{1-x}$Nb$_x$O$_3$ are seen together with those from the LaAlO$_3$ substrate, indicating that incoherent hetero-epitaxial growth of the target materials occurred for all $x$ compositions. The peak positions of the diffraction spots from each composition correspond well with the cubic line ($q_1/q_3 = -3$), indicating that no epitaxial strain was induced in the films. It should be noticed that a slight tetragonal distortion was observed in the $x = 0.4$ ($c/a = 1.0057$) and 0.5 ($c/a = 1.0050$) samples. From the RSMs of the SrTi$_{1-x}$Nb$_x$O$_3$ films, we extracted their lattice parameters using the formula $a = (2\pi q_1^2 \Delta q_1 \Delta q_2)^{1/3}$. Figure 2(b) plots the lattice parameters of the SrTi$_{1-x}$Nb$_x$O$_3$ film as a function of $x$: we observed an M-shaped trend, along with a general increase in the lattice parameter with increasing $x$. In order to analyze the changes in lattice parameter, we calculated the average ionic radii in the crystal structure and used Shannon’s ionic radii as a comparison.\textsuperscript{36} $\text{Ti}^{4+}$ (60.5 pm), $\text{Ti}^{3+}$ (67.0 pm), Nb$^{4+}$ (68.0 pm), and Nb$^{5+}$ (64.0 pm). In the ranges of $0.05 \leq x \leq 0.3$ and $x \geq 0.6$, the observed lattice parameters closely followed the heterovalent substitution line, suggesting that two Ti$^{4+}$ or Nb$^{4+}$ ions are substituted by adjacent (Ti$^{3+}$/Nb$^{5+}$) ions.\textsuperscript{27} On the other hand, at $x = 0.4$ and 0.5, the observed lattice parameter corresponded well with the isovalent substitution line; moreover, at $x = 0.5$, the B-site occupation of [Ti$^{4+}$/Nb$^{5+}$] was almost 100%, as shown in Fig. 2(c).

In order to further clarify the occupation of B-sites by [Ti$^{4+}$/Nb$^{4+}$], we analyzed the atomic arrangement and electronic structure of the $x = 0.5$ film by STEM and EELS. Figure 3(a) shows a cross-sectional HAADF-STEM image of an SrTi$_{0.5}$Nb$_{0.5}$O$_3$ film. Periodical mismatch dislocations with an interval of ~8.5 nm were seen at the heterointerfaces. If the strain in the thin-film were fully relaxed by such misfit dislocations, it would be possible to calculate the spacing between dislocations ($d$) from $d = b/\delta$, where $b$ is the Burgers vector and $\delta$ is the lattice mismatch between thin-film and substrate.\textsuperscript{28} Using the lattice parameters obtained from XRD ($\delta = (q_{x\text{sub}} - q_{x\text{film}})/q_{x\text{film}} = +0.0435$), a dislocation spacing of 8.7 nm was estimated, suggesting that the dislocations do fully relax the strain in the film.

Although superspots originating from (111) diffraction are often observed in AB$_{0.5}$B$^{0.5+}$O$_3$ compositions that crystallize in B-site–ordered double perovskite structures,\textsuperscript{29} these were not observed in the SrTi$_{0.5}$Nb$_{0.5}$O$_3$ film [Fig. 3(b)], most likely due to the slight tetragonal distortion of the crystal structure. Figure 3(c) shows the EELS spectra acquired around the Ti L$_2$ edge for compositions with different $x$ values.\textsuperscript{32,33} As was observed for SrTi$_{0.5}$Nb$_{0.5}$O$_3$, the peak intensity ratio A/B was also plotted for comparison. In the Ti L$_2$ edge spectra (c), $t_{2g}$ and $e_g$ peak splitting was clearly observed for Ti L$_2$, indicating that the dominant valence state of Ti is 4+. In the O K edge spectra (d), two intense peaks (assigned as A and B) were clearly seen, with the intensity of peak B being higher than A, which was noted to be a characteristic feature of Nb$^{4+}$ in a previous study;\textsuperscript{31} the peak intensity ratio A/B was calculated to be 0.66, which roughly corresponds with the Nb$^{4+}$ spectrum (0.66). From these results, we conclude that isovalent substitution of Ti$^{4+}$/Nb$^{4+}$ dominates in the $x = 0.5$ composition.

We then measured $\sigma$, $n$, and $\mu_{\text{Hall}}$ by Hall effect measurements. Generally, $\sigma$ was observed to increase with increasing $x$, as shown in Fig. 4(a); additionally, it was noted that there was a sharp increase in $\sigma$ between $0.5 < x < 0.6$, suggesting the existence of an electronic phase boundary at $x \sim 0.5$. $n$ was also measured to increase with increasing $x$, which almost corresponds with the nominal value ($n = x$ in a unit cell) [Fig. 4(b)]. For the mobility, as shown in Fig. 4(c), $\mu_{\text{Hall}}$ for compositions with $x < 0.5$ remained almost constant at ~6 cm$^2$/V·s, which is consistent with other reported values.\textsuperscript{32,33} As was observed for $\sigma$, a sharp increase in $\mu_{\text{Hall}}$ from ~5 cm$^2$/V·s to ~10 cm$^2$/V·s was observed between compositions with $x = 0.5$ and $x = 0.6$, after which the values steadily increased to ~12 cm$^2$/V·s at $x = 1$ (cf. a value of ~14 cm$^2$/V·s measured for this composition in a previous study\textsuperscript{19}). From these results, we can conclude that the small $\mu_{\text{Hall}}$ dominates the electronic phase boundary at $x \sim 0.5$.

\caption{Crystallographic characterization of the SrTi$_{1-x}$Nb$_x$O$_3$ epitaxial films on a (001) LaAlO$_3$ single crystal substrate. (a) X-ray reciprocal space mappings around the (103) diffraction spot of the SrTi$_{1-x}$Nb$_x$O$_3$ epitaxial films. The location of the LaAlO$_3$ diffraction spot, ($q_1/2\pi, q_2/2\pi$) = (−2.64, 7.92), corresponds with the pseudo-cubic lattice parameter of LaAlO$_3$ ($a = 0.379$ nm). Red symbols (+) indicate the peak positions of the SrTi$_{1-x}$Nb$_x$O$_3$ epitaxial films. (b) Changes in the lattice parameters of the SrTi$_{1-x}$Nb$_x$O$_3$ films (circles, left axis), with superimposed isovalent/heterovalent substitution lines (black line: isovalent substitution, gray line: heterovalent substitution, right axis), calculated using Shannon’s ionic radii.\textsuperscript{36} (c) Change in the B-site occupation by [Ti$^{4+}$/Nb$^{4+}$] derived from the data in (b).}
\end{figure}
In order to further elucidate the origin of the electronic phase boundary, we took measurements of $S$ across the composition range: by measuring the values of both $n$ and $S$, we were then able to calculate the density of states effective mass ($m^*$), as outlined in equations (1)–(3) below. Not surprisingly, $|S|$ was found to monotonically decrease with increasing $x$, as shown in Fig. 4(d). We then calculated $m^*$ using the following relation between $n$ and $S$,

$$S = -k_B \frac{r(r+2)F_{r+1} (\xi)}{(r+1)F_r (\xi)} - \xi,$$

(1)

where $k_B$, $\xi$, $r$, and $F_r$ are the Boltzmann constant, chemical potential, scattering parameter of relaxation time, and Fermi integral, respectively. $F_r$ is given by

$$F_r (\xi) = \int_0^\infty \frac{x^r e^{-x}}{1 + e^{x-\xi}} dx,$$

(2)

and $n$ by

$$n = 4\pi \left( \frac{2m^* k_B \theta}{h^2} \right)^{3/2} F_2 (\xi),$$

(3)

where $h$ and $T$ are the Planck constant and absolute temperature, respectively. Using the equations (1)–(3), we obtained the values of $m^*$, which are presented in Fig. 4(e): a step-like decrease of $m^*$ was observed with increasing $x$, as shown in Fig. 4(d). We then calculated $m^*$ using the following relation between $n$ and $S$,

$$S = C_0 k_B e r + 2F_r (\xi) - n,$$

(4)

where $C_0$, $n$, $r$, and $F_r$ are the Boltzmann constant, chemical potential, scattering parameter of relaxation time, and Fermi integral, respectively. $F_r$ is given by

$$F_r (\xi) = \int_0^\infty \frac{x^r e^{-x}}{1 + e^{x-\xi}} dx,$$

(5)

and $n$ by

$$n = 4\pi \left( \frac{2m^* k_B \theta}{h^2} \right)^{3/2} F_2 (\xi),$$

(6)

where $h$ and $T$ are the Planck constant and absolute temperature, respectively. Using the equations (4)–(6), we obtained the values of $m^*$, which are presented in Fig. 4(e): a step-like decrease of $m^*$ was observed with increasing $x$, as shown in Fig. 4(d). We then calculated $m^*$ using the following relation between $n$ and $S$,

$$S = C_0 k_B e r + 2F_r (\xi) - n,$$

(7)

where $C_0$, $n$, $r$, and $F_r$ are the Boltzmann constant, chemical potential, scattering parameter of relaxation time, and Fermi integral, respectively. $F_r$ is given by

$$F_r (\xi) = \int_0^\infty \frac{x^r e^{-x}}{1 + e^{x-\xi}} dx,$$

(8)

and $n$ by

$$n = 4\pi \left( \frac{2m^* k_B \theta}{h^2} \right)^{3/2} F_2 (\xi),$$

(9)

where $h$ and $T$ are the Planck constant and absolute temperature, respectively. Using the equations (4)–(9), we obtained the values of $m^*$, which are presented in Fig. 4(e): a step-like decrease of $m^*$ was observed with increasing $x$, as shown in Fig. 4(d). We then calculated $m^*$ using the following relation between $n$ and $S$,
speculate that there is a percolation threshold for compositions with \( x \approx 0.3 \) and that parabolic Ti 3 d orbitals dominate electron conduction when \( x < 0.3 \), whereas the Nb 4 d orbitals determine electron conduction when \( x > 0.3 \). Similar percolation threshold was observed in the other insulating/conducting oxide system.

Finally, the relaxation time, \( \tau \), was extracted from the \( \mu_{\text{Hall}} \) and \( m^* \) values (\( = e \cdot \tau \cdot m^* \): these results are shown in Fig. 4(f). The \( \tau \) values in the range \( 0.05 \leq x \leq 0.2 \) are \( \sim 4 \) fs, followed by a drop, reaching a minimum value of \( \sim 2 \) fs at \( x = 0.5 \). After \( x = 0.5 \), \( \tau \) initially increases sharply to 3.5 fs at \( x = 0.6 \), with a much more gradual increase with \( x \) composition in the range \( 0.6 \leq x \leq 0.9 \). Finally, there was a slight drop in \( \tau \) value to 3.2 fs for the \( x = 1 \) composition. The trend’s trough shape, in particular, the sharp increase of \( \tau \) from \( \sim 2 \) to \( \sim 3.5 \) fs in the range \( 0.5 < x < 0.6 \), clearly indicates that \( \tau \) dominates the electronic phase boundary at \( x \approx 0.5 \). Yamamoto et al. reported that \( \tau \) of the SrTi\(_{0.8}\)Nb\(_{0.2}\)O\(_3\) epitaxial films was significantly reduced by Sr-site substitution with Ca or Ba, due to the occurrence of tetragonal lattice distortion: since slight tetragonal distortion was observed in the \( x = 0.4 \) and 0.5 films, as shown in Fig. 2(a), we speculate that the tetragonal distortion also minimizes the \( \tau \) in this set of thin-films.

FIG. 5. Thermoelectric phase diagram for the SrTiO\(_3\)-SrNbO\(_3\) solid solution system. The thermoelectric power factor (\( S^2 \sigma \)) of the SrTiO\(_3\)-SrNbO\(_3\) solid solution system is plotted, alongside the previously reported values. The \( x \) dependence of \( S^2 \sigma \) is shown in the inset. The system’s thermoelectric phase boundaries are clearly seen at \( x \approx 0.3 \) and \( \sim 0.5 \).

FIG. 6. Calculated density of states (DOS) for SrTi\(_{1-x}\)Nb\(_x\)O\(_3\) ss (\( x = 0, 0.25, 0.5, 0.75, \) and 1). (a) Total DOS, (b) and (c) orbital-projected DOS. The energy origin was set at the Fermi level, \( E_F \), indicated by the dotted line.
Then, we plotted the thermolectric power factor ($\Sigma^2-\sigma$) of the SrTi$_{1-x}$Nb$_x$O$_3$ solid solution with values reported in the previous studies (Fig. 5). In the region around $x \sim 0.05$ where the observed data (red circle/red line) overlap with the reported values from$^{10}$ (white circle/grey line), the two data sets match well. There are two local maxima in $\Sigma^2-\sigma$—first at $x \sim 0.05$ ($\sim$2.5 mW m$^{-1}$ K$^{-2}$) and second at $\sim$0.55 ($\sim$0.9 mW m$^{-1}$ K$^{-2}$). We also observed two thermolectric phase boundaries in the system, occurring in the ranges around $x \sim 0.3$ and $x \sim 0.5$, as shown in the inset. Since $S$ is strongly correlated with $m^*$, the sharp decrease in $m^*$ at $x \sim 0.3$ [Fig. 4(e)] accounts for the concomitant reduction in $S$. In addition, the small value of $\tau$ at $x \sim 0.5$ (where $\tau$ was measured to reach a minimum) contributed greatly to the observed reduction in $\sigma$. In conclusion, in order to maximize the thermolectric performance of the SrTi$_{1-x}$Nb$_x$O$_3$ solid solution, the use of compositions with $x \leq 0.2$ would be the most suitable.

Finally, we calculated the band structures for SrTi$_{1-x}$Nb$_x$O$_3$ ($x = 0, 0.25, 0.5, 0.75,$ and 1) in order to elucidate the origin of the two electronic phase boundaries using $2 \times 2 \times 2$ supercell model structures. Figure 6 summarizes the resultant total and orbital-projected density of states (DOS) of the SrTi$_{1-x}$Nb$_x$O$_3$ compositions around the bandgap. The energy origin was set at the Fermi level, $E_F$ (dotted line). $E_F$ was found to increase gradually with the increase in $x$. When $x > 0$, the $E_F$ was located higher energy side of the conduction band minimum (Ti 3$d$ – Nb 4$d$ hybridized orbital), indicating that the compositions in this range are degenerate semiconductors (or metals). The similar band structure between $x = 0$ and $x = 0.25$ compositions is consistent with the similar $m^*$ and $\tau$ values recorded experimentally from films with $x < 0.3$. Meanwhile, both $x = 0.5$ and $x = 0.75$ SrTi$_{1-x}$Nb$_x$O$_3$ were found to possess a tail-like feature in the DOS below the $E_F$. The major component of the tail at $x = 0.75$ was the Ti 3$d$, whereas at $x = 0.5$, Ti 3$d$ and Nb 4$d$ orbitals both made comparable contributions to the observed feature.

The former corroborates the suggestion from the experimental results that Ti$^{3+}$ ions are present [Figs. 2(b) and 2(c)]. However, the latter is completely different from the experimentally obtained fact that isovalent substitution of Ti$^{4+}$/ Nb$^{3+}$ dominates in the $x = 0.5$ composition. As mentioned above, we did not observe any superstructure such as B-site ordered Sr$_2$TiNbO$_6$. Although we used special quasi-random structures (SQSs) in the case of the band calculations of SrTi$_{1-x}$Nb$_x$O$_3$ ($x = 0.25$, 0.5, and 0.75), B-site ordering still remained due to the finite cell size ($2 \times 2 \times 2$ supercell of cubic perovskite). This should be the main reason that the calculation result of $x = 0.5$ does not reflect the experimentally obtained solid solution crystal. Moreover, the characteristic decrease in $\tau$ measured for compositions around $x = 0.5$ (and was not observed when $x > 0.6$) may imply that the electrons from the Nb 4$d$ orbitals in the tail-like DOS do not contribute to the electrical conductivity of the SrTi$_{1-x}$Nb$_x$O$_3$ solid solution.

We should note that there are not only the consistent results between our calculations and experiments discussed above but inconsistent results of the valence states of the Ti and Nb ions in $x = 0.25$ and 0.5 SrTi$_{1-x}$Nb$_x$O$_3$. This discrepancy may be partly originated from the restriction of the supercell size, which may be insufficient to represent the random B-site ionic arrangements. Larger supercell model would help to understand the origin of the two electronic phase boundaries.

IV. SUMMARY

In summary, we have clarified the thermolectric phase diagram for the SrTi$_{1-x}$Nb$_x$O$_3$ (0.05 $\leq x \leq 1$) solid solution system through characterization of epitaxial thin-films. We observed two thermolectric phase boundaries in the system, which originate from the combination of a step-like decrease in carrier effective mass at $x \sim 0.3$ with the local minimum carrier relaxation time at $x \sim 0.5$. The origins of these electronic phase boundaries were analyzed in the context of isovalent/heterovalent B-site substitution. Parabola-shaped Ti 3$d$ orbitals dominate electron conduction for compositions $x < x < 0.3$, whereas the Nb 4$d$ orbitals dominate when $x > 0.3$. At $x \sim 0.5$, a tetragonal distortion of the lattice occurs, in which the B-site is composed of predominantly [Ti$^{4+}$/Nb$^{3+}$] ions, leading to the formation of tail-like impurity bands in the density of states, which maximizes electron scattering.

These findings may prove useful in further improving and optimizing the thermolectric performance of SrTi$_{1-x}$Nb$_x$O$_3$. Moreover, the analyses of the B-site ion valence states in this study provide valuable information that could be used in the design of other functional materials based on transition metal oxides.
