General Introduction

Quaternary carbon stereogenic centers, which have four different carbon substituents, are attractive synthetic targets found in many bioactive compounds and pharmaceutical intermediates (Figure 1). Thus, development of efficient methods to provide quaternary carbon stereogenic centers in enantiomerically pure states is highly important. However, the enantioselective installation of quaternary carbon stereogenic centers, especially in a catalytic manner, represents one of the most challenging tasks in organic synthesis. This difficulty is due to the increased steric demands of the C–C bond forming process, and thus may require harsh reaction conditions. Moreover, the relatively similar steric environment presented by non-hydrogen substituents is an obstacle to achieving high levels of enantiotopic face selectivity.

1. Construction of Quaternary Carbon Stereogenic Centers through Transition Metal Catalyzed Allylic Substitution Reactions

1.1. Introduction

Since its first report in the 70s, transition metal catalyzed enantioselective allylic substitutions have been known to be a versatile method for a wide range of asymmetric C–C bond formation reactions.\(^1\) Advances over the past two decades demonstrate that this protocol is one of the most powerful tools for producing quaternary carbon stereogenic centers. While this approach was historically carried out using Pd catalysts, it was subsequently expanded to Ir-, Rh-, Mo- and Cu-catalyzed reactions. The choice of metals leads to different regioselectivities and expansion of the scope of nucleophiles in the allylation reaction. The following sections outline these methods, categorized into the construction of quaternary carbon stereogenic centers on (i) the nucleophile side (Scheme 1), and (ii) the allyl electrophile side (Scheme 2).

1.2. Construction of Quaternary Carbon Stereogenic Centers on Nucleophile Side

1.2.1. Allylic Substitution with Soft Carbon Nucleophiles

1.2.1.1. Pd-Catalysis

Pd-catalyzed enantioselective allylic substitution of “soft” stabilized or non-stabilized carbon nucleophiles such as carbonyl enolates and enamines is the most common method for construction of α-quaternary carbonyl compounds.¹ The typical reaction involves the well-known π-allylpalladium intermediate derived from the oxidative addition of allyl substrates to palladium(0) species (Figure 2). Subsequent attack of the carbon nucleophile to the electrophilic π-allylpalladium species results in the allylic substitution product and regeneration of the palladium(0) species.

![Figure 2. General Principle of Pd-Catalyzed Enantioselective Allylic Substitution](image)

Since nucleophilic attack generally occurs at the sterically less hindered side of the π-allylpalladium species, the reaction of allylic electrophiles that are substituted at only one terminus provides linear and achiral products. Thus, quaternary carbon stereogenic centers are generated by the reaction of prochiral carbon nucleophiles bearing three distinct substituents. A typical example of such nucleophiles is a trisubstituted enolate, generated by deprotonation of the α-proton of a carbonyl compound (Scheme 3).

![Scheme 3. Pd-Catalyzed Asymmetric Allylic Substitution](image)

In 1996, Sawamura and Ito reported that the allylation of α-cyano esters proceeded with excellent enantioselectivity under the influence of a Pd/Rh-dual catalytic system using AnisTRAP.
(L1) as a ligand (Scheme 4). In this reaction, the palladium complex activates the allyl electrophile by forming the π-allylpalladium species, while the rhodium complex is coordinated by the cyano group of the cyanoester substrate and to control the enantioselectivity.

**Scheme 4.** Pd-Rh Two-Component Catalytic System

Soon after, Trost reported an asymmetric allylic substitution in cyclic systems. The use of the Trost-type ligand (L2) in the reaction between 2-carboalkoxycyclohexanone derivatives and allyl acetates afforded the corresponding product with high ee (Scheme 5). The author demonstrated the enantio- and diastereoselective reaction of 1,3-dimethyl allylic substrates, which could provide a symmetrical π-allyl intermediate.

**Scheme 5.** Asymmetric Allylic Substitution of β-Ketoester

Inspired by these pioneering works, chemists have expanded the scope of nucleophiles to the use of α,α-disubstituted amides, β-hydroxyacrylate aldehydes, and α,α-disubstituted aldehydes.

Compared with the aforementioned carbonyl compounds containing α'-blocking groups or α-electron withdrawing groups, position-selective enolate generation of unsymmetrical ketones with multiple acidic α-protons can be particularly challenging. Pd-catalyzed decarboxylative allylation of allyl enol carbonates or allyl β-ketoesters provides an efficient method to generate ketone
enolates as a single isomer.\(^7\)

The first example of asymmetric decarboxylative allylic alkylation of allyl enol carbonates was reported by Stoltz in 2006.\(^8\) The reaction provides synthetically important \(\alpha\)-quaternary cyclohexanones from simple alkanone derivatives in a highly enantioenriched form in the presence of the PHOX ligand (L3) (Scheme 6).

**Scheme 6. Decarboxylative Allylation of Allyl Enol Carbonates**

Pd-catalyzed decarboxylative allylic alkylation were expanded to the use of racemic allyl β-ketoesters (Scheme 7).\(^9\) Stoltz employed a catalytic double enantioselective decarboxylative allylation of the racemic bis-β-ketoester in the total synthesis of (−)-cyanthiwigin F (Scheme 8).\(^10,11\) This stereoconvergent approach allows the generation of two quaternary carbon stereogenic centers on the cyclohexadione ring with high enantioselectivity. A decarboxylative allylic alkylation in acyclic systems has also been reported.\(^12\)

**Scheme 7. Decarboxylative Allylation of β-Ketoesters**
1.2.1.2. Mo, Ir, and Rh Catalysis

In contrast to the case of palladium, allylic substitutions with unsymmetric allylic substrates catalyzed by other transition metals preferentially form branched products through attack of the nucleophile at the more substituted carbon of the allylmetal moiety (Scheme 9). Therefore, these catalyst systems enable simultaneous stereocontrol of both prochiral carbon nucleophiles and prochiral allylic electrophiles under appropriate conditions. The reactions catalyzed by Mo, Ir and Rh are shown below.

Scheme 9. Branch-Selective Asymmetric Allylic Substitution

The Mo-catalyzed reaction was reported by Trost in 2006. The enantioselective allylation of prochiral 3-alkyl oxindole, with L4 as a chiral ligand, provided chiral 3,3’-dialkyl oxindoles (Scheme 10). The author expanded this strategy to a regio-, diastereo- and enantioselective version with cinnamyl carbonate. This method was later extended to the use of β-cyanoesters as prochiral nucleophiles (Scheme 11).

Scheme 10. Mo-Catalyzed Allylic Substitution of Oxindoles
In 2013, Carreira developed the enantio- and diastereodivergent synthesis of γ,σ-unsaturated aldehydes bearing vicinal quaternary/tertiary carbon stereogenic centers (Scheme 12). The asymmetric α-allylation of allylic alcohols with α,α-disubstituted aldehydes was enabled by the dual catalyst system of the Ir/phosphoramidite (L6) complex and a cinchona-alkaloid-derived primary amine. All four stereoisomers of the product can be accessed through selection of the suitable pair of chiral iridium complex and chiral amine, which activate the allylic alcohol and aldehyde, respectively. The in situ generated chiral enamine attacks the allyliridium complex to give the desired product.

Shortly after this article was published, Stoltz developed the diastereo- and enantioselective allylation of α-substituted β-ketoesters catalyzed by the Ir/phosphoramidite complex (Scheme 13). The reaction provides vicinal quaternary/tertiary carbon stereogenic centers in cyclic systems. Linear β-ketoesters are also applicable to this protocol (Scheme 14).

In 2015, Evans demonstrated the allylic alkylation of lithiated α-substituted benzyl nitriles with allyl carbonates using a rhodium complex that was modified by a chiral monodentate phosphite ligand (Scheme 15). This is the first report of the direct asymmetric alkylation of a nitrile anion. 15-Crown-5 was used as a deaggregating agent to affect the equilibrium between the C- and N-metalated forms.

Later, this strategy was expanded to the use of α-branched aldehydes by the same author. The direct asymmetric allylic substitution of aldehyde enolates affords synthetically useful α-quaternary aldehydes (Scheme 16). Mechanistic studies revealed that high levels of enantioselectivity could be achieved even from a mixture of (E)- and (Z)-enolates of the aldehydes.
1.2.2. Asymmetric Allylic Dearomatization

Aromatic compounds are highly abundant and readily available materials. Transition metal catalyzed asymmetric allylic dearomatizations serve as a very attractive strategy for construction of polycyclic or spirocyclic compounds containing quaternary carbon stereogenic centers.\textsuperscript{13, 22}

In 2006, Trost reported that the Pd-catalyzed enantioselective C3-allylation of 3-substituted indoles with allylic alcohols employing the chiral anthracene-derived ligand L\textsubscript{9} provided the corresponding chiral 3,3-disubstituted indolenines (Scheme 17).\textsuperscript{23}

Scheme 17. Pd-Catalyzed Asymmetric Allylic Dearomatization of 3-Substituted Indoles

Inspired by Trost’s pioneering work, You and co-workers developed an intramolecular allylic dearomatization with tryptamine-derived indolyl allyl carbonate under the influence of the Ir/phosphoramidite catalyst system (Scheme 18).\textsuperscript{24} The reaction allowed the synthesis of chiral six-membered ring spirocyclic compounds from readily available starting materials and construction of two contiguous stereogenic centers. This protocol was later applied to the construction of enantioenriched five-membered ring spirocyclic compounds\textsuperscript{25} and nine-membered rings.\textsuperscript{26}
Scheme 18. Asymmetric Synthesis of Six-Membered-Ring Spiroindolenines

![Scheme 18](image)

Phenols are usually used as oxygen nucleophiles in transition metal catalyzed allylic substitution reactions, but there are few examples of C-allylation. Hamada developed the Pd-catalyzed asymmetric allylic dearomatization reaction of para-substituted phenol derivatives containing an allylic carbonate (Scheme 19). The reaction gave spirocyclohexadienones with high enantioselectivity.

Scheme 19. Pd-Catalyzed Intramolecular Asymmetric Allylic Dearomatization of Phenols

![Scheme 19](image)

Later, construction of quaternary carbon stereogenic centers through the asymmetric allylic dearomatization reaction of naphthols was also achieved.

1.3. Construction of Quaternary Carbon Stereogenic Centers on Allyl Electrophile Side

1.3.1. Cu-Catalyzed S<sub>N</sub>2′ Allylic Cross-Coupling with Organometallic Reagents

Copper is one of the cheapest and most readily available transition metals. Cu-catalyzed allylic cross-coupling has enjoyed special attention to promote the coupling of organometallic reagents due to its high S<sub>N</sub>2′ affinity (Figure 3, left). Hence, Cu-catalysis is complementary to other metal-catalyzed processes. The general principle of Cu-catalyzed allylic cross-coupling is described in Figure 3 (right). The reaction proceeds via initial formation of the organocopper(I)
species, which is generated by transmetallation between the organometallic reagent and the Cu(I) complex. Subsequent S_N2’ reaction between the organocopper(I) species and the prochiral allylic substrate provides the cross-coupling product containing a vinyl group. Quaternary carbon stereogenic centers are obtained by the reaction of isomerically pure γ,γ-disubstituted allylic substrates.

**Figure 3.** General Principle of Cu-Catalyzed Enantioselective Allylic Cross-Coupling

The last dozen years have witnessed significant progress in Cu-catalyzed enantioselective allylic cross-coupling of various carbon nucleophiles, which provide quaternary carbon stereogenic centers. In the early years in this research area, highly reactive organometallic reagents such as organolithium-, Grignard-, organoaluminum- and diorganozinc reagents attracted much attention.

### 1.3.1.1 Cu-Catalyzed Allylic Cross-Coupling with Organolithium-, Grignard-, Organoaluminum-, and Diorganozinc Reagents

In 2001, Hoveyda reported the allylic alkylation of γ,γ-disubstituted allylic phosphates with dialkylzinc reagents using the peptide-base ligand (L10) (Scheme 20).³⁰ Later, the author improved the reaction system³¹ and found that the bidentate NHC-based chiral ligand Ag complex (1) enforced higher enantioselectivity with lower loading of the copper catalyst (Scheme 21).³²

**Scheme 20.** Dialkylzinc Reagents
Crévisy and Mauduit demonstrated the allylation reaction with readily available alkylgrignards utilizing the bidentate hydroxyalkyl NHC ligand (L11) derived from a chiral amino acid pool (Scheme 22). The reaction provides the corresponding products with high regio- and enantioselectivities.

As described by Feringa, alkyl lithium reagents also engaged in the Cu/phosphoramidite-catalyzed allylic substitution (Scheme 23).

Not only C(sp³), but also C(sp³) and C(sp), organometallic reagents are able to participate in these reactions. Hoveyda showed that the allylic alkylation of \textit{in situ} prepared alkenylaluminum reagents with γ,γ-disubstituted allylic phosphates provided 1,4-dienes bearing chiral quaternary centers (Scheme 24). High regio- and enantioselectivities were observed in the presence of the Cu catalyst, which were derived from the chiral bidentate sulfonate-based NHC (2).
The same author applied this methodology to the use of aryl- and alkynylaluminum reagents. The reaction provides enantioenriched diaryl- or 1,4-enyne compounds (Schemes 25 and 26).

Recently, Feringa found that aryllithium reagents can be applied to the reaction with allyl bromides.38

1.3.1.2 Cu-Catalyzed Allylic Cross-Coupling with Organoboron Reagents

While reactions with the aforementioned highly reactive nucleophiles provide the corresponding quaternary carbon stereogenic centers with high regio- and enantioselectivities, poor to moderate functional group tolerance even at cryogenic temperature can be a problem. To address this shortcoming, the use of organoboron reagents, which are much less reactive but easier to handle and more tolerant to functional groups, has recently emerged as a superior alternative.
In 2011, Shintani and Hayashi discovered that a combination of a Cu-catalyst, which was modified by a Mauduit-type chiral NHC ligand, and MeONa enabled the enantioselective allylic cross-coupling between arylboronic acid esters and allylic phosphates. Improvement of enantioselectivity and expansion of substrate scope were later achieved with the new chiral NHC ligand (L13) (Scheme 27). Control experiments revealed that the hydroxy group in the ligand substituent was crucial for achieving high reactivity and selectivity.

Scheme 27. Arylboronates

In addition to arylboronates, other types of organoboron reagents are also employed for Cu-catalyzed enantioselective allylic substitutions. In 2012, Hoveyda applied alkenylboronic acid esters to the coupling reaction with allylic phosphates, based on the author’s previous work on alkenylaluminum reagents (see Scheme 24) (Scheme 28). The reaction allowed effective delivery of sensitive organic functional groups that were not compatible with organoaluminum chemistry. The utility of this protocol was demonstrated by the asymmetric synthesis of the Pummerer ketone from an enantioenriched 1,4-diene (Scheme 29).

Scheme 28. Alkenylboronates
Scheme 29. Asymmetric Synthesis of Pummerer Ketone

In a contemporaneous report, Hoveyda disclosed that the allylic cross-coupling of allenylboron reagents led to chiral allenes bearing quaternary carbon stereogenic centers with good to high enantioselectivity (Scheme 30). More recently, Hoveyda utilized propargylboronic acid pinacol esters in the allylation reaction to afford 1,5-enynes containing quaternary carbon stereogenic centers (Scheme 31).

Scheme 30. Allenylboronates

Scheme 31. Propargylboronates

1.3.2. Pd-Catalyzed Branch-Selective Allyl-Allyl Coupling with Allylboronates

Morken found that allylboronates were useful reagents for Pd-catalyzed enantioselective allylic substitutions. The reaction between racemic tertiary allylic carbonates and allylboronic acid pinacol esters was effectively catalyzed by the Pd/MeO-furyl-BIPHEP complex to provide 1,5-
dienes containing quaternary carbon stereogenic centers in highly regio- and enantioselective fashion (Scheme 32). Mechanistic experiments suggest that the reaction proceeded by way of 3,3'-reductive elimination of the bis-(η1-allyl)palladium intermediates.

\]

3,3'-reductive elimination

**1.3.3. Asymmetric C(sp\(^2\))–H Allylation with Azoles**

In 2016, Ohmiya and Sawamura showed that azoles participate in the Cu-catalyzed asymmetric C(sp\(^2\))–H allylation of γ,γ-disubstituted allylic phosphates to form quaternary carbon stereogenic centers at the position α to the heteroaromatic ring (Scheme 33). The use of the chiral naphthol-carbene ligand (L18), which was developed by the Ohmiya and Sawamura group, enabled the reaction. A variety of azoles were used directly without premetalation of the C(sp\(^2\))–H bond.

\]

**1.3.4. Ir-Catalyzed Enantioselective Synthesis of α-Quaternary Carboxylic Acids**

Most recently, Stoltz achieved the construction of a quaternary carbon stereogenic center on the allyl electrophile side through an Ir-catalyzed enantioselective allylic alkylation of the masked acyl cyanide (MAC) reagent, which is an umpolung synthon of a carboxylic acid, with γ,γ-disubstituted allyl carbonates (Scheme 34). Hydrolysis of the MAC-functionalized product provided direct access to the corresponding enantioenriched α-quaternary carboxylic acids.
2. Overview of this Thesis

The author developed Cu-catalyzed enantioselective allylic substitution reactions for the construction of quaternary carbon stereogenic centers. All of them proceeded under mild conditions with good to excellent enantioselectivities and showed high functional group compatibility. In chapters 1 and 2, the author discusses the reactions between alkyl-9-BBN, an alkylboron reagent, and allyl chlorides. In chapter 1, intermolecular allylic cross-coupling under the catalysis of a Cu(I) system is described. In chapter 2, construction of chiral cyclic compounds through intramolecular allylic cross-coupling of alkyl-9-BBN reagents with allyl chlorides is shown. In chapter 3, a highly regio- and enantioselective three-component coupling of isocyanides, hydrosilanes, and γ,γ-disubstituted allylic phosphates is described.

2.1. Construction of Quaternary Stereogenic Carbon Centers through Copper-Catalyzed Enantioselective Allylic Cross-Coupling with Alkylboranes (Chapter 1)

As mentioned in section 1.3.1.2., Cu-catalyzed allylic cross-coupling of organoboron reagents is a powerful synthetic method for functionalized quaternary carbon stereogenic centers. Despite many efforts, the applicable reagents have been limited to aryl-, alkenyl-, allenyl- and propargylboron compounds. The use of alkylboron reagents has not been achieved.

In chapter 1, the author describes an enantioselective allylic cross-coupling of primary γ,γ-disubstituted allyl chlorides with alkyl-9-BBN reagents under the influence of an in situ generated chiral Cu(I)/DTBM-MeO-BIPHEP catalyst and EtOK system (Scheme 35). 3,5-Di-β-butyl-4-methoxyphenyl (DTBM) substituents on the phosphorus atoms were essential not only for enantiocontrol but also for catalytic activity. The reaction provides quaternary carbon stereogenic centers containing three sp³-alkyl groups and a vinyl group. A possible reaction pathway involving addition/elimination of a neutral alkylcopper(I) species with the allyl chloride substrate is proposed.

2.2. Copper-Catalyzed Enantioselective Intramolecular Alkylboron Allylic Alkylation (Chapter 2)

In chapter 2, the author describes enantioselective reductive cyclization of allyl chlorides tethered to a terminal alkene that goes through 9-BBN hydroboration of the terminal alkene followed by copper-catalyzed enantioselective intramolecular allylic alkylation with a new chiral phosphoramidite ligand (Scheme 36). The reaction afforded functionalized chiral six-membered ring compounds containing tertiary or quaternary carbon stereogenic centers substituted with a vinyl group with high enantioselectivities.

Scheme 36. Cu-Catalyzed Enantioselective Intramolecular Allylic Substitution
2.3. Synthesis of $\alpha$-Quaternary Formimides and Aldehydes through Copper-Catalyzed Asymmetric Three-Component Coupling Reaction of Isocyanides, Hydrosilanes, and Allylic Electrophiles (Chapter 3)

In chapter 3, the author describes that a highly regio- and enantioselective Cu-catalyzed three component coupling reaction of hydrosilane, isocyanide, and $\gamma,\gamma$-disubstituted allyl phosphate was enabled by the use of the chiral naphthol-carbene ligand (L17), developed by Sawamura and Ohmiya group (Scheme 37). $\alpha$-Quaternary formimides and aldehydes were provided by allylic alkylation with a formimidoyl copper species, which is a formyl anion equivalent produced by 1,1-insertion of isocyanide to a hydride copper species. Due to the mild reaction conditions, high functional group compatibility was observed. The formimidoyl group and the vinyl group in the three component coupling product can be utilized for further chemical transformations.

Chapter 1

Construction of Quaternary Stereogenic Carbon Centers through Copper-Catalyzed Enantioselective Allylic Cross-Coupling with Alkylboranes

A combination of an in-situ generated Cu(I)-DTBM-MeO-BIPHEP chiral catalyst system and the EtOK base enabled the enantioselective SN2’-type allylic cross-coupling between alkylborane (alkyl-9-BBN) reagents and γ,γ-disubstituted primary allyl chlorides with enantiocontrol at a useful level. This protocol allowed the use of terminal alkenes as nucleophile precursors, thus representing a formal reductive allylic cross-coupling of terminal alkenes. A reaction pathway involving addition-elimination of a neutral alkylcopper(I) species with the allyl chloride substrate is proposed.
Introduction

Catalytic enantioselective construction of all-carbon quaternary stereogenic centers in acyclic systems is one of the biggest challenges in organic synthesis. One of the obstacles is a low reactivity due to the steric repulsion that occurs in the carbon–carbon bond formation step. It is also difficult to discriminate the enantiotopic faces due to steric congestion and the diminished steric difference between the non-hydrogen substituents. To this end, transition metal catalyzed enantioselective allylic substitutions with organometallic nucleophiles such as organolithium, Grignard, diorganozinc or triorganoaluminum reagents have proven to be effective strategies.

Organoboron compounds have also been used for enantioselective construction of all-carbon quaternary stereogenic centers through allylic substitution, making this strategy more tolerant to various functional groups. However, applied organoboron reagents are limited to aryl-, alkenyl-, allenyl-, and allylboron (propargyl) compounds; the methodology has not yet been generalized to allow the reaction of non-allylic alkylboron nucleophiles.

Earlier, Sawamura and Ohmiya reported the enantioselective SN2'-type reaction between alkylboranes and γ-monosubstituted primary allyl chlorides under catalysis of the Cu(I)-DTBM-SEGPHOS system (eq. 1). However, the protocol was limited to the construction of tertiary carbon stereogenic centers using γ-monosubstituted primary allylic substrates. The authors reported that a combination of an in situ generated Cu(I)-DTBM-MeO-BIPHEP chiral catalyst system and the EtOK base enabled the enantioselective SN2'-type allylic cross-coupling between alkylborane (alkyl-9-BBN) reagents and γ,γ-disubstituted primary allyl chlorides with enantiomeric purity at a useful level.

The reaction generates a quaternary carbon stereogenic center branched with three sp3-alkyl groups and a vinyl group. The overall protocol employs terminal alkenes as nucleophile precursors, thus representing a formal reductive allylic cross-coupling of terminal alkenes.

Results and Discussion

Discovery of the reaction and screening of conditions

The author’s earlier investigation on the copper-catalyzed enantioselective reaction between alkylboranes and γ-monosubstituted primary allyl chlorides indicated that introducing 3,5-di-t-butyl-4-methoxyphenyl (DTBM) substituents on the phosphorus atoms of chiral bisphosphines was important for promotion of the reaction. The author assumed that the introduction of the...
DTBM substituents would induce the deaggregation of the alkylcopper(I) species to form a catalytically active monomeric copper complex. On the basis of this consideration, he examined copper complexes prepared from CuOTf·(toluene)0.5 (10 mol %) and various DTBM-substituted chiral bisphosphine ligands for catalytic activity, γ-regioselectivity, and enantioselectivity in the reaction of γ,γ-disubstituted allyl chloride (E)-3a with alkylborane 2a in the presence of EtOK in 1,4-dioxane/dichloromethane (DCM) (1:3) at 25 °C over 20 h (3a/2a/EtOK 1:1.25:1.1) (Table 1, entries 1–4). As in the previous study with γ-monosubstituted allyl chlorides, the alkylborane 2a was prepared in advance through hydroboration of 3,4-dimethoxy-1-allylbenzene (1a) with (9-BBN-H)2 (3a/1a/B 1:1.3:1.25) at 60 °C over 1 h and was used without purification. The conversion of 1a into 2a with a full consumption of 9-BBN-H was confirmed by 1H and 11B NMR spectroscopy. The amount of EtOK base was adjusted so that the borane 2a was in a slightly excess (2a/EtOK 1.1:1) to ensure a full consumption of EtOK for the formation of CuOEt and borate (2a') species (see below). Accordingly, yields of allylation product 4aa were calculated based on the allyl chloride 3a. Specifically, the catalyst prepared from the DTBM-substituted TunePHOS-type chiral bisphosphine (L1) did not promote the reaction at all (entry 1). (R)-DTBM-BINAP (L2) induced only low catalytic activity, γ-selectivity, and enantioselectivity (entry 2). (R)-DTBM-SEGPHOS (L3), which exhibited high performance in the previously reported reaction with γ-monosubstituted primary allyl chlorides (eq. 1), imparted moderate γ-selectivity (γ/α 6:1) and enantioselectivity (47% ee), but the product yield was lower than that with L2 (entry 3). To the author’s delight, the use of (R)-DTBM-MeO-BIPHEP (L4) led to a significant improvement in the regioselectivity and enantioselectivity (entry 4). The alkylation occurred at the disubstituted γ-carbon atom of 3a (γ/α >20:1), constructing the all-carbon quaternary stereogenic center with 83% ee in favor of the formation of (S)-4aa (si-face attack), albeit still with a low product yield. These results suggest that the catalytic activity, γ-selectivity, and enantioselectivity of this reaction are very sensitive to the dihedral angle of the axially chiral biaryl scaffolds in the Cu(I)–bisphosphine complexes.

The product yield with the Cu–L4 system could be increased to 56% by changing the solvent to THF/DCM (1:3) with the enantioselectivity almost unchanged (81% ee) (Table 1, entry 5). The yield was further improved to 65% by conducting the reaction at 15 °C with a increased amount of the 2a/EtOK reagent (3a/2a/EtOK 1/1.7/1.5) (entry 6).

NMR Studies

The mixture of (9-BBN-H)$_2$ (12.1 mg, 0.05 mmol) and 3,4-dimethoxy-1-allylbenzene (18.1 µl, 0.11 mmol) in THF (0.04 mL) was stirred at 60 °C for 1 hour to prepare 2a [δ 69.6 (11B), Figure 1. See also Figure 4 for the $^1$H NMR spectrum]. Next, the THF solution of 2a was added to a vial containing EtOK (8.8 mg, 0.1 mmol) and CH$_2$Cl$_2$ (0.12 mL) at 25 °C, and the resulting yellow suspension was stirred at 25 °C for 10 min. The $^{11}$B NMR spectrum of the suspension showed a peak that corresponds to a tetravalent borate 2a' (δ –3.1) (Figure 2. See also Figure 5. for the $^1$H NMR spectrum). Subsequently, the suspension was added to a vial containing CuOTf·(toluene)$_{0.5}$ (25.8 mg, 0.1 mmol, B/Cu 1:1) and L4 (115.2 mg, 0.1 mmol), and the resulting yellow suspension was stirred at 25 °C for 15 min: the peak of the borate 2a' disappeared completely and a signal that corresponds to 9-BBN-OEt appeared at δ 55.6 as a major peak in a $^{11}$B NMR spectrum (Figure 3. see also Figure 6. for a $^1$H NMR spectrum).

Substrates

The reaction of Z-configured allyl chloride (Z)-3a under the conditions optimal for the reaction of (E)-3a (Table 1, entry 6) provided (R)-4aa, the antipode of the product derived from (E)-3a, with 61% ee in 85% yield (eq. 2).¹⁰,¹¹ This enantioselectivity is lower than that for the reaction of (E)-3 (vide infra for discussion on enantioselection models).

Various terminal alkenes having different functional groups such as acetal, ester, chloro, silyl ether...
and benzyl ether moieties in the aliphatic chain were compatible with this protocol (entries 1–6).

Ethylene also served as a suitable substrate (Table 2, entry 7). Ethylene also served as a suitable substrate (Table 2, entry 7). This reaction delivered an ethyl group to the fully substituted γ-carbon atom of 3a with enantioselectivity at a useful level.

The scope of γ,γ-disubstituted allyl chlorides (3) is also shown in Table 2 (entries 8–10). An additional trisubstituted alkene moiety in the allylic substrate 3b was tolerated for the formation of diene 4ab (entry 8). The copper catalyst system enabled the enantioselective coupling of allyl chlorides having two alkyl substituents of almost equal steric demands at the γ-position (entries 9 and 10). For example, allyl chloride 3c having ethyl and phenylethyl groups at the γ-position reacted with a high enantioselectivity (81% ee) (entry 9). Replacing the ethyl group at the γ-position of 3c with a propyl group caused only a slight reduction in the enantioselectivity (entry 10).

Table 2. Scope of enantioselective allylic cross-coupling with alkylboranes.[a]

Considerations for reaction pathways

A possible catalytic cycle for the γ-selective allylic coupling is illustrated in Figure 7.5,6a-c As proposed for the Cu-catalyzed enantioselective reaction between alkylboranes and γ-monosubstituted primary allyl chlorides, the active organocopper species is likely in the form of a neutral organocopper(I) species (C) rather than a monooorganoheterocuprate, as EtOK is consumed for the formation of borate 2' and the copper center bearing the alkyl ligand and the bisphosphine ligand (L4) is coordinatively saturated upon alkene coordination.12 Therefore, the reaction would proceed through addition–β-elimination with the neutral organocopper(I) species B. The enantioselection would occur at transition states of the R1–Cu addition across the C–C double bond of 3 (C → D-TS → (E →) A + 4 + 9-BBN-OEt).

[a] Conditions of hydroboration: 1, 0.35 mmol; (9-BBN-H)2, 0.17 mmol (1/B 1.05:1); 60 °C, 1 h. 2 (0.34 mmol) was used without purification. Conditions of enantioselective coupling reaction: (E)-3, 0.2 mmol; 2, 0.34 mmol; EtOK, 0.3 mmol: CuOTf·(toluene)0.5, 10 mol %; (R)-DTBM-MeO-BIPHEP (L4), 10 mol %; THF/DCM (1:3, 0.8 mL); 15 °C, 20 h. [b] Yield of the isolated product. [c] Constitutional isomer ratio γ/α >20:1 (determined by 'H NMR analysis of the crude product). [d] The enantiomeric excess was determined by HPLC analysis. [e] Constitutional isomer ratio γ/α >10:1. [f] Diastereomeric ratio (1:1).
Theformationof the $\alpha$-coupling product in thereaction with ($R$)-DTBM-BINAP (L2) or ($R$)-DTBM-SEGPHOS (L3) might be due to the formation of alkyl(ethoxo)cuprate species upon dissociation of one or two P atoms of the chiral ligands. Such cuprate species would undergo oxidativeaddition with 3 to form an isomeric mixture of $[[\sigma+\pi]-\text{allyl}]$copper(III) species with a C–Cu $\sigma$ bond either at the $\alpha$ or $\gamma$ carbon atoms. Reductive elimination of these allylcopper(III) intermediates may form a mixture of the $\alpha$- and $\gamma$-coupling product as a minor product.$^{16,17}$

**Figure 7.** Possible Catalytic Cycle.

The author proposes enantioselection models depicted in Figure 8 based on the fact that the reactions of $E$- and $Z$-isomers of 3a gave the antipodes of 4, respectively, the former showing higher enantioselectivity (Table 1, entry 6 vs. eq 2). In the $\pi$-complex C (see Figure 1), the allyl chloride substrate (3) bound to the tetrahedral copper center is in proximity to the two P-substituents Ar$^1$ and Ar$^3$, which are axial and equatorial substituents, respectively, of the bisphosphine-Cu chelate ring. The axial substituent Ar$^1$ points toward the substrate more than the equatorial Ar$^3$. R$_1$ and R$_3$ indicate the larger and smaller $\gamma$-substituents of 3, respectively. C-1, which leads to the major enantiomer of 4 in the reaction of ($E$)-3, has steric repulsion only between R$_3$ and Ar$^3$, while the corresponding $\pi$-complex (C-2) leading to the minor enantiomer has larger steric repulsions between the ClCH$_2$ group and Ar$^1$ and between Ar$^3$ and R$_1$. A similar discussion should be applicable for the transition state D-TS.

In the case of the reaction of ($Z$)-3, the $\pi$-complex (C-3) leading to the major enantiomer, the antipode of the product from C-1, has a steric repulsion between Ar$^3$ and R$_1$, which should be larger than the steric repulsion that occurs in C-1 (R$_1$ vs. R$_3$). On the other hand, the steric repulsion
between Ar³ and Rₘ in C-4 should be smaller than that between Ar³ and R₁ in C-2. These considerations also match the observed trend that the enantioselectivity gradually decreased with the increase of the size of the Rₘ substituent of (E)-3 (Table 2, entries 1, 9, and 10). This can be explained by the increasing steric repulsion between Ar³ and Rₘ in C-1.

![Models for Enantiodiscrimination](image)

**Figure 8.** Models for Enantiodiscrimination.

**Conclusion**

In summary, the author have developed an Sₜ₂’-type enantioselective allylic cross-coupling between alkyl-9-BBN reagents and γ,γ-disubstituted primary allyl chlorides under catalysis of a Cu(I)-DTBM-MeO-BIPHEP system to deliver enantioenriched chiral products containing quaternary carbon stereogenic centers branched with three sp³-alkyl groups and a vinyl group. This protocol allowed the use of terminal alkenes as nucleophile precursors, thus representing a formal reductive allylic cross-coupling of terminal alkenes.

**Experimental Section**

**Instrumentation and Chemicals**

NMR spectra were recorded on a Varian Gemini 2000 spectrometer, operating at 300 MHz for ¹H NMR, and a JEOL ECX-400, operating at 100.5 MHz for ¹³C NMR, 128 MHz for ¹¹B NMR and 161.8 MHz for ³¹P NMR. Chemical shift values for ¹H and ¹³C are referenced to Me₂Si and the residual solvent resonances, respectively. Chemical shift values for ¹¹B is referenced to BF₃·OEt₂ (δ 0 ppm). Chemical shifts are reported in δ ppm. Mass spectra were obtained with Thermo Fisher Scientific Exactive, JEOL JMS-T100LP or JEOL JMS-700TZ at the Instrumental
Analysis Division, Equipment Management Center, Creative Research Institution, Hokkaido University. Elemental analysis was performed at the Instrumental Analysis Division, Equipment Management Center, Creative Research Institution, Hokkaido University. HPLC analyses were conducted on a HITACHI ELITE LaChrom system with a HITACHI L-2455 diode array detector. IR spectra were recorded on a Perkin-Elmer Spectrum One. TLC analyses were performed on commercial glass plates bearing 0.25-mm layer of Merck Silica gel 60F254. Silica gel (Kanto Chemical Co., Silica gel 60 N, spherical, neutral) was used for column chromatography. Melting points were measured on a Yanaco MP-500D apparatus. Gel permeation chromatography (GPC) was performed by LC-908 (Japan Analytical Industry Ltd., two in-line JAIGEL-2H, CHCl3, 3.5 mL/min, UV and RI detectors).

All reactions were carried out under nitrogen or argon atmosphere. Materials were obtained from commercial suppliers or prepared according to standard procedures unless otherwise noted. 9-Borabicyclo[3,3,1]nonane dimer (9-BBN-H)2, CuOTf·(toluene)0.5, EtOK, (R)-DTBM-MeO-BIPHEP and (R)-DTBM-BINAP were purchased from Aldrich Chemical Co., stored under nitrogen, and used as it is. (R)-DTBM-SEGPHOS was purchased from Strem Chemicals Inc., stored under nitrogen, and used as it is. Dichloromethane (DCM) was purchased from Kanto Chemical Co., stored over 4Å molecular sieves under nitrogen. 1,4-Dioxane was purchased from Kanto Chemical Co., distilled from sodium/benzophenone and stored over 4Å molecular sieves under nitrogen. Terminal alkenes 1a–h are known compounds.

Preparation of Allyl Chlorides (3)

Preparation of γ,γ-disubstituted (E)-allyl chlorides 3a, c and d (Scheme 1). The preparation of 3a is representative (Scheme 1). To a solution of Cul (1.8 g, 9.6 mmol) and TMEDA (3.6 mL, 24 mmol) in THF (1.0 mL) was added 2-phenylethylmagnesium bromide (0.7 M in THF, 13.7 mL, 9.6 mmol) at −40 °C, and the resulting mixture was stirred at −40 °C for 30 min. To the mixture was added ethyl 2-butynoate (0.9 g, 8 mmol) at −78 °C, and the mixture was stirred at −78 °C for 2 h. Saturated NH4Cl aq was added and the mixture was allowed to warm to room temperature. The resulting slurry was diluted with EtOAc (50 mL) and washed with H2O and brine. The organic layer was separated and dried over MgSO4. Then, the drying agent was removed by filtration, and the resulting solution was evaporated under reduced pressure. The residue was purified by flash chromatography on silica gel (0–10% EtOAc/hexane) provided alkynoate (1.7 g, 7.6 mmol) in 95% yield.

To a stirred solution of alkynoate (1.7 g, 7.6 mmol) in DCM was dropped DIBAL-H (16.4 mL in 1.02 M hexane solution, 16.7 mmol) at −78 °C and the reaction was continued for 30 min at the same temperature. Sat. NH4Cl was added and the mixture was vigorously stirred for 10 min. Solid
was filtered through celite pad and the filtrate was extracted with ether. The crude product was purified by flash chromatography on silica gel (10–20% EtOAc/hexane) to give allylic aldohol (1.2 g, 6.6 mmol) in 87% yield.

To a solution of allylic alcohol (1.2 g, 6.6 mmol) in DCM (13.2 mL), NCS (1.0 g, 7.3 mmol) and PPh₃ (2.0 g, 7.9 mmol) were sequentially added at 0 °C. After being stirred at rt for 2 h, the solvent was removed under reduced pressure, and then residue was filtered through a pad of celite with EtOAc as an eluent. The filtrate was evaporated under reduced pressure. The residue was purified through flash chromatography on silica gel (hexane) followed by Kugelrohr distillation provided 3a (1.1 g, 5.6 mmol) in 80% yield.

**Scheme 1.** Preparation of γ,γ-disubstituted (E)-allyl chlorides 3a, c and d

**Preparation of γ,γ-disubstituted (E)-allyl chloride 3b (Scheme 2).** To a solution of geraniol (1.5 g, 10 mmol) in DCM (20 mL), NCS (1.5 g, 11 mmol) and PPh₃ (3.1 g, 12 mmol) were sequentially added at 0 °C. After being stirred at rt for 2 h, the solvent was removed under reduced pressure, and then residue was filtered through a pad of celite with hexane as an eluent. The filtrate was evaporated under reduced pressure. The residue was purified by Kugelrohr distillation to provid 3b (1.4 g, 8 mmol) in 80% yield.

**Scheme 2.** Preparation of γ,γ-Disubstituted (E)-Allyl Chloride 3b

**Characterization Data for Allyl Chlorides**

Allyl chlorides (E)-3a,b are found in the literature.
(Z)-(5-Chloro-3-methyl-3-penten-1-yl)benzene [(Z)-3a]

Colorless Oil. **IR** (neat) 697, 1253, 1454, 1495, 2940, 3027 cm⁻¹. **¹H NMR** (300 MHz, CDCl₃) δ 0.93 (s, 3H), 2.38–2.43 (m, 2H), 2.70–2.77 (m, 2H), 3.88 (d, J = 8.1 Hz, 2H), 5.46 (t, J = 8.1 Hz, 1H), 7.17–7.22 (m, 3H), 7.26–7.32 (m, 2H). **¹³C NMR** (100.5 MHz, CDCl₃) δ 23.51, 33.92, 34.28, 40.65, 121.74, 126.05, 128.38 (2C), 141.45, 141.76. **HRMS–EI** (m/z): [M]+ calcld for C₁₂H₁₅Cl, 194.08623; found, 194.08630.

(E)-(5-Chloro-3-ethyl-3-penten-1-yl)benzene (3c)

Colorless Oil. **IR** (neat) 697, 739, 1252, 1454, 2935, 2967 cm⁻¹. **¹H NMR** (300 MHz, CDCl₃) δ 1.05 (t, J = 7.5 Hz, 3H), 2.14–2.21 (m, 2H), 2.33–2.38 (m, 2H), 2.70–2.76 (m, 2H), 4.11 (d, J = 8.1 Hz, 2H), 5.44 (t, J = 8.1 Hz, 1H), 7.17–7.21 (m, 3H), 7.25–7.31 (m, 2H). **¹³C NMR** (100.5 MHz, CDCl₃) δ 13.31, 23.44, 34.33, 38.18, 40.68, 120.13, 125.88, 128.33 (2C), 141.77, 147.86. **HRMS–EI** (m/z): [M]+ calcld for C₁₃H₁₇Cl, 208.10188; found, 208.10202.

(E)-[3-(2-Chloroethylidene)hexyl]benzene (3d)

Colorless Oil. **IR** (neat) 697, 746, 1315, 1454, 2870, 2959 cm⁻¹. **¹H NMR** (300 MHz, CDCl₃) δ 0.93 (t, J = 7.5 Hz, 3H), 1.40–1.53 (m, 2H), 2.10–2.15 (m, 2H), 2.31–2.37 (m, 2H), 2.70–2.76 (m, 2H), 4.11 (d, J = 8.1 Hz, 2H), 5.47 (t, J = 8.1 Hz, 1H), 7.16–7.21 (m, 3H), 7.25–7.31 (m, 2H). **¹³C NMR** (100.5 MHz, CDCl₃) δ 14.08, 21.65, 32.38, 34.36, 38.51, 40.85, 120.95, 125.87, 128.32 (2C), 141.78, 145.96. **HRMS–EI** (m/z): [M]+ calcld for C₁₄H₁₉Cl, 222.11753; found, 222.11773.

Procedure for Copper-Catalyzed Enantioselective Allylic Cross-Coupling with Alkylboranes.

The reaction in Table 1, entry 6 is representative. 3,4-Dimethoxy-1-allylbenzene (1a) (93.4 µL, 0.54 mmol) and (9-BBN-H)₂ (64.2 mg, 0.26 mmol) were placed in a vial containing a magnetic stirring bar. The vial was sealed with a Teflon®-coated silicon rubber septum and the vial was evacuated and filled with argon. THF (0.3 mL) was added to the vial, and then the mixture was stirred at 60 °C for 1 h to prepare an alkylborane. Meanwhile, CuOTf·(toluene)₀·₅ (7.8 mg, 0.03
mmol), (R)-DTBM-MeO-BIPHEP (L4) (35.5 mg, 0.03 mmol) and EtOK (39.9 mg, 0.45 mmol) were placed in another vial. This vial was sealed with a Teflon®-coated silicon rubber septum and then evacuated and filled with argon. After DCM (0.9 mL) was added to the vial, the mixture was stirred at 25 °C for 1 h. Next, the alkylborane solution was transferred to the vial containing the Cu(I)–L4 complex. Next, allyl chloride (E)-3a (58.5 mg, 0.3 mmol) was added. After 20 h stirring at 15 °C, diethyl ether was added to the mixture. The mixture was filtered through a short plug of silica gel, which was then washed with diethyl ether. After the solvent was removed under reduced pressure, flash chromatography on silica gel (0–3% EtOAc/hexane) provided 4aa (66.0 mg, 0.20 mmol) at 81% ee in 65% yield.

**Characterization Data for Allylic Cross-Coupling Products**

(S)-1,2-Dimethoxy-4-(4-methyl-4-phenethyl-5-hexen-1-yl)benzene (4aa)

![Structure of 4aa](image)

The product (S)-4aa was purified by flash chromatography on silica gel (0–2% EtOAc/hexane) followed by GPC (CHCl3) (65% isolated yield). Colorless Oil. IR (neat) 698, 1030, 1236, 1260, 1515, 2935 cm⁻¹. ¹H NMR (300 MHz, CDCl₃) δ 1.03 (s, 3H), 1.35–1.40 (m, 2H), 1.55–1.65 (m, 4H), 2.45–2.55 (m, 4H), 3.85 (s, 3H), 3.87 (s, 3H), 4.94 (d, J = 17.4 Hz, 1H), 5.04 (d, J = 10.8 Hz, 1H), 5.74 (dd, J = 17.4, 10.8 Hz, 1H), 6.70–6.72 (m, 2H), 6.79 (m, 1H), 7.13–7.18 (m, 3H), 7.24–7.29 (m, 2H). ¹³C NMR (100.5 MHz, CDCl₃) δ 22.50, 26.21, 30.67, 36.20, 39.58, 40.51, 42.93, 55.78, 55.88, 111.08, 111.64, 111.99, 120.11, 125.54, 128.29 (2C), 135.30, 143.28, 146.86, 146.99, 148.68. HRMS–EI (m/z): [M]⁺ calcd for C₂₃H₃₀O₂, 338.22458; found, 338.22391. [α]D²³ +5.81 (c 1.10, CHCl₃).

HPLC analysis [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 99.5:0.5, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 106.7 min for R isomer and 112.5 min for S isomer] revealed that the enantiomeric excess of 4aa was 81% ee. The absolute configuration of 4aa was assigned by consideration of the stereochemical pathway.

(S)-2-(6-Methyl-6-phenethyl-7-octen-1-yl)-1,3-dioxane (4ba)

![Structure of 4ba](image)
The product 4ba was purified by flash chromatography on silica gel (0–2% EtOAc/hexane) (79% isolated yield). Colorless Oil. IR (neat) 698, 909, 996, 1143, 2849, 2929 cm⁻¹. ¹H NMR (300 MHz, CDCl₃) δ 1.01 (s, 3H), 1.26–1.43 (m, 8H), 1.54–1.64 (m, 5H), 2.08 (m, 1H), 2.46–2.52 (m, 2H), 3.76 (dt, J = 12.0, 2.4 Hz, 2H), 4.08–4.13 (m, 2H), 4.50 (t, J = 5.1 Hz, 1H), 4.93 (dd, J = 17.4, 1.5 Hz, 1H), 5.02 (dd, J = 10.8, 1.5 Hz, 1H), 5.74 (dd, J = 17.4, 10.8 Hz, 1H), 7.15–7.19 (m, 3H), 7.25–7.30 (m, 2H). ¹³C NMR (100.5 MHz, CDCl₃) δ 22.55, 23.87, 23.96, 25.84, 30.26, 30.70, 35.23, 39.58, 40.71, 42.97, 66.88, 102.39, 111.76, 125.49, 128.28 (2C), 143.37, 147.09. HRMS – EI (m/z): [M]+ calcd for C₂₁H₃₂O₂, 316.24023; found, 316.24002. [α]D⁰ +2.06 (c 1.08, CHCl₃).

The ee value (90% ee) was determined by chiral HPLC analysis of the aldehyde derivative obtained by the ozonolysis followed by reduction with Me₂S from 4ba [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/CHIRALCEL® OD-H column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 96:4, 0.7 mL/min, 40 °C, 220 nm UV detector, retention time = 54.1 min for R isomer and 55.7 min for S isomer]. The absolute configuration of 4ba was assigned by consideration of the stereochemical pathway.

**Derivatization of 4ba.** Ozone was bubbled into a solution of 4ba (15.8 mg, 0.05 mmol) in diethyl ether (5.0 mL) at −78 °C. After the starting material was completely disappeared (monitored by TLC), dimethyl sulfide (0.1 mL) was added and the mixture was allowed to warm to room temperature and it was further stirred at the room temperature for 2 h. The mixture was diluted with EtOAc and washed with H₂O and brine. The organic layer was separated and dried over MgSO₄. Then, the drying agent was removed by filtration, and the resulting solution was evaporated under reduced pressure. The residue was purified by flash chromatography on silica gel (0–4% diethyl ether/DCM) provided the aldehyde derivative (3.2 mg, 0.01 mmol).

![Diagram](image)

**[(S)-6-Methyl-6-phenethyl-7-octen-1-yl Pivalate (4ca)](image)**

The product 4ca was purified by flash chromatography on silica gel (0–2% EtOAc/hexane) (66% isolated yield). Colorless Oil. IR (neat) 698, 1284, 1151, 1727, 2862, 2935 cm⁻¹. ¹H NMR (300 MHz, CDCl₃) δ 1.03 (s, 3H), 1.19 (s, 9H), 1.29–1.32 (m, 6H), 1.52–1.64 (m, 4H), 2.47–2.53 (m, 2H), 4.04 (t, J = 6.6 Hz, 2H), 4.95 (d, J = 17.4 Hz, 1H), 5.04 (d, J = 11.1 Hz, 1H), 5.75 (dd, J
= 17.4, 11.1 Hz, 1H), 7.15–7.19 (m, 3H), 7.25–7.30 (m, 2H). 13C NMR (100.5 MHz, CDCl3) δ 22.46, 23.72, 26.77, 27.20 28.64, 30.70, 38.72, 39.61, 40.87, 43.02, 64.44, 111.95, 125.55, 128.30 (2C), 143.31, 146.94, 178.69. HRMS–EI (m/z): [M]+ calcd for C22H34O2, 330.25588; found, 330.25630. [α]D25 +7.36 (c 0.58, CHCl3).

The ee value (81% ee) was determined by chiral HPLC analysis of the aldehyde derivative obtained by the ozonolysis followed by reduction with Me2S from 4ca [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/CHIRALCEL® OD-H column, 4.6 mm × 250 mm/CHIRALCEL® OD-H column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 96:4, 0.7 mL/min, 40 °C, 220 nm UV detector, retention time = 29.7 min for R isomer and 30.6 min for S isomer] (4ca was converted to the corresponding aldehyde according to the procedure for the derivatization of 4ba). The absolute configuration of 4ca was assigned by consideration of the stereochemical pathway.

(S)-(9-Chloro-3-methyl-3-vinyl)nonyl)benzene (4da)

The product 4da was purified by flash chromatography on silica gel (hexane) followed by GPC (CHCl3) (80% isolated yield). Colorless Oil. IR (neat) 696, 909, 1453, 1495, 2858, 2930 cm⁻¹. 1H NMR (300 MHz, CDCl3) δ 1.03 (s, 3H), 1.26–1.48 (m, 6H), 1.52–1.61 (m, 4H), 1.72–1.79 (m, 2H), 2.47–2.53 (m, 2H), 2.75 (dd, J = 11.1, 1.5 Hz, 1H), 7.15–7.20 (m, 3H), 7.25–7.30 (m, 2H). 13C NMR (100.5 MHz, CDCl3) δ 22.49, 23.85, 26.87, 29.67, 30.70, 32.62, 39.60, 40.82, 42.98, 45.16, 111.89, 125.53, 128.29 (2C), 143.32, 146.99. HRMS–EI (m/z): [M]+ calcd for C18H27Cl, 278.1803; found, 278.18100. [α]D25 +6.49 (c 0.30, CHCl3).

The ee value (86% ee) was determined by chiral HPLC analysis of the aldehyde derivative obtained by the ozonolysis followed by reduction with Me2S from 4da [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/CHIRALCEL® OD-H column, 4.6 mm × 250 mm/CHIRALCEL® OD-H column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 96:4, 0.7 mL/min, 40 °C, 220 nm UV detector, retention time = 39.6 min for R isomer and 41.3 min for S isomer] (4da was converted to the corresponding aldehyde according to the procedure for the derivatization of 4ba). The absolute configuration of 4da was assigned by consideration of the stereochemical pathway.
(S)-Triisopropyl[(6-methyl-6-phenethyl-7-octen-1-yl)oxy]silane (4ea)

The product 4ea was purified by flash chromatography on silica gel (0–1% EtOAc/hexane) (85% isolated yield). Colorless Oil. IR (neat) 679, 910, 1106, 1463, 2864, 2938 cm⁻¹. ¹H NMR (300 MHz, CDCl₃) δ 1.05–1.12 (m, 24H), 1.21–1.32 (m, 6H), 1.50–1.64 (m, 4H), 2.47–2.53 (m, 2H), 3.66 (t, J = 6.6 Hz, 2H), 4.94 (dd, J = 17.4, 1.5 Hz, 1H), 5.04 (dd, J = 11.1, 1.5 Hz, 1H), 5.75 (dd, J = 17.4, 11.1 Hz, 1H), 7.15–7.17 (m, 3H), 7.24–7.29 (m, 2H). ¹³C NMR (100.5 MHz, CDCl₃) δ 11.99, 18.03, 22.56, 23.85, 26.62, 30.71, 33.01, 39.60, 40.92, 42.97, 63.41, 111.76, 125.50, 128.28 (2C), 143.39, 147.14. HRMS–ESI (m/z): [M+H]+ calcd for C₂₆H₄₇OSi, 403.33907; found, 403.33838.

The ee value (83% ee) was determined by chiral HPLC analysis of the aldehyde derivative obtained by the ozonolysis, reduction with Me₂S from 4ea [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/CHIRALCEL® OD-H column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 98:2, 0.3 mL/min, 40 °C, 220 nm UV detector, retention time = 17.9 min for R isomer and 18.6 min for S isomer] (4ea was converted to the corresponding aldehyde according to the procedure for the derivatization of 4ba). The absolute configuration of 4ea was assigned by consideration of the stereochemical pathway.

2-[(S)-7-Methyl-7-phenethyl-8-noneno-1-yl]oxy|tetrahydro-2H-pyran (4fa)
(Diastereomeric ratio 1:1)

The product 4fa was purified by flash chromatography on silica gel (0–2% EtOAc/hexane) (70% isolated yield). Colorless Oil. IR (neat) 1022, 1032, 1119, 2859, 2931 cm⁻¹. ¹H NMR (300 MHz, CDCl₃) δ 1.02 (s, 3H), 1.23–1.36 (m, 6H), 1.54–1.87 (m, 12H), 2.47–2.53 (m, 2H), 3.38 (m, 1H), 3.51 (m, 1H), 3.73 (m, 1H), 3.87 (m, 1H), 4.58 (m, 1H), 4.94 (d, J = 17.4 Hz, 1H), 5.03 (d, J = 11.1 Hz, 1H), 5.75 (dd, J = 17.4, 11.1 Hz, 1H), 7.15–7.18 (m, 3H), 7.25–7.30 (m, 2H). ¹³C NMR (100.5 MHz, CDCl₃) δ 19.70, 22.57, 23.96, 25.49, 26.25, 29.75, 30.29, 30.72, 30.78, 39.61, 40.86, 42.97, 62.36, 67.67, 98.84, 111.76, 125.51, 128.29 (2C), 143.39, 147.14. HRMS–EI (m/z): [M]+ calcd for C₂₃H₃₆O₂, 344.27153; found, 344.27045. [α]D²⁸ +5.94 (c 0.87, CHCl₃).

The ee value (86% ee) was determined by chiral HPLC analysis of the acetal derivative obtained by the ozonolysis, reduction with Me₂S followed by acetalization from 4fa
[CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/CHIRALCEL® OD-H column, 4.6 mm × 250 mm/CHIRALCEL® OD-H column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 96:4, 0.7 mL/min, 40 °C, 220 nm UV detector, retention time = 39.6 min for R isomer and 41.2 min for S isomer]. The absolute configuration of 4fa was assigned by consideration of the stereochemical pathway.

**Derivatization of 4fa.** Ozone was bubbled into a solution of 4fa (34.4 mg, 0.1 mmol) in diethyl ether (5.0 mL) at −78 °C. After the starting material was completely disappeared (monitored by TLC), dimethyl sulfide (0.1 mL) was added and the mixture was allowed to warm to room temperature and it was further stirred at the room temperature for 2 h. The mixture was diluted with EtOAc and washed with H2O and brine. The organic layer was separated and dried over MgSO4. Then, the drying agent was removed by filtration, and the resulting solution was evaporated under reduced pressure. The residue was purified by flash chromatography on silica gel (50–75% DCM/hexane) provided the aldehyde derivative (13.9 mg, 0.04 mmol).

To a solution of the aldehyde (13.9 mg, 0.04 mmol) in MeOH (0.1 mL) was added p-TsOH (4.6 mg, 0.0024 mmol) at room temperature. The resulting mixture was stirred at room temperature for 2 h (monitored by TLC) and diluted with H2O. The aqueous layer was extracted with EtOAc (three times). The combined organic layer was washed with water and brine, and then was dried and concentrated. The crude product was purified by flash column chromatography (DCM) yielded the acetal derivative (9.3 mg, 0.03 mmol).

(S)-[7-(Benzyloxy)-3-methyl-3-vinylheptyl]benzene (4ga)

The product 4ga was purified by flash chromatography on silica gel (0–2% EtOAc/hexane) (68% isolated yield). Colorless Oil. IR (neat) 696, 733, 1102, 1454, 2862, 2936 cm⁻¹. ¹H NMR (300 MHz, CDCl₃) δ 1.03 (s, 3H), 1.23–1.37 (m, 4H), 1.52–1.64 (m, 4H), 2.47–2.52 (m, 2H), 3.46 (t, J = 6.6 Hz, 2H), 4.50 (s, 2H), 4.94 (d, J = 17.4 Hz, 1H), 5.04 (d, J = 10.8 Hz, 1H), 5.75 (dd, J = 17.4, 10.8 Hz, 1H), 7.14–7.18 (m, 3H), 7.24–7.34 (m, 7H). ¹³C NMR (100.5 MHz, CDCl₃) δ 20.68, 22.51, 30.47, 30.70, 30.62, 40.69, 42.94, 70.34, 72.87, 111.93, 125.53, 127.48, 127.65 (2C), 128.30 (2C), 138.64, 143.33, 146.97. HRMS–ESI (m/z): [M+Na]⁺ calcd for C₂₃H₃₀ONa, 345.21889; found, 345.21869. [α]D²² +8.32 (c 0.43, CHCl₃).
HPLC analysis [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 95:5, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 49.1 min for R isomer and 51.7 min for S isomer] revealed that the enantiomeric excess of 4ga was 81% ee. The absolute configuration of 4ga was assigned by consideration of the stereochemical pathway.

(S)-(3-Ethyl-3-methyl-4-penten-1-yl)benzene (4ha)

The product 4ha was purified by flash chromatography on silica gel (hexane) followed by GPC (CHCl₃) (63% isolated yield). Colorless Oil. IR (neat) 696, 752, 910, 1454, 2933, 2965 cm⁻¹. ¹H NMR (300 MHz, CDCl₃) δ 0.82 (t, J = 7.5 Hz, 3H), 1.01 (s, 3H), 1.39 (q, J = 7.5 Hz, 2H), 1.51–1.61 (m, 2H), 2.47–2.53 (m, 2H), 4.95 (dd, J = 17.4, 1.5 Hz, 1H), 5.05 (dd, J = 10.8, 1.5 Hz, 1H), 5.74 (dd, J = 17.4, 10.8 Hz, 1H), 7.15–7.21 (m, 3H), 7.25–7.29 (m, 2H). ¹³C NMR (100.5 MHz, CDCl₃) δ 8.38, 21.99, 30.74, 33.07, 39.77, 42.62, 112.02, 125.52, 128.30 (2C), 143.44, 146.83. HRMS–EI (m/z): [M]+ calcd for C₁₄H₂₀, 188.15650; found, 188.15651. [α]D²⁰ +16.69 (c 0.63, CHCl₃)

The ee value (71% ee) was determined by chiral HPLC analysis of the alcohol derivative obtained by the ozonolysis followed by reduction with NaBH₄ from 4ha [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/CHIRALCEL® OD-H column, 4.6 mm × 250 mm/CHIRALCEL® OD-H column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 96:4, 0.7 mL/min, 40 °C, 220 nm UV detector, retention time = 39.6 min for R isomer and 44.5 min for S isomer]. The absolute configuration of 4ha was determined by optical rotation of the alcohol derivative. [α]D²² –8.91 (c 0.10, CHCl₃). {lit²⁰, (S) isomer, 96% ee, [α]D²⁰ –12.48 (c 0.125, CH₂Cl₂)}.

Derivatization of 4ha. Ozone was bubbled into a solution of 4ha (7.4 mg, 0.04 mmol) in MeOH/diethyl ether (1:10, 5.0 mL) at −78 °C. After the starting material was completely disappeared (monitored by TLC), NaBH₄ (15.1 mg, 0.4 mmol) was added and the mixture was allowed to warm to room temperature and it was further stirred at the room temperature for 1 h. The mixture was quenched with water. The aqueous layer was extracted with EtOAc (three times). The combined organic layer was washed with water and brine, and then was dried and concentrated. Purification by column chromatography (silica gel, 5–15% EtOAc/hexane) yielded the alcohol derivative (3.8 mg, 0.02 mmol).
(S)-4-(4,8-Dimethyl-4-vinyl-7-non-1-enyl)-1,2-dimethoxybenzene (4ab)

The product 4ab was purified by flash chromatography on silica gel (0–2% EtOAc/hexane) followed by GPC (CHCl₃) (54% isolated yield). Colorless Oil. IR (neat) 1031, 1235, 1260, 1515, 2854, 2933 cm⁻¹. ¹H NMR (300 MHz, CDCl₃) δ 0.95 (s, 3H), 1.25–1.35 (m, 4H), 1.46–1.61 (m, 5H), 1.67 (s, 3H), 1.80–1.89 (m, 2H), 2.51 (t, J = 7.5 Hz, 2H), 3.86 (s, 3H), 3.88 (s, 3H), 4.87 (dd, J = 17.4, 1.5 Hz, 1H), 4.97 (dd, J = 10.8, 1.5 Hz, 1H), 5.08 (m, 1H), 5.68 (dd, J = 17.4, 10.8 Hz, 1H), 6.69–6.72 (m, 2H), 6.79 (m, 1H). ¹³C NMR (100.5 MHz, CDCl₃) δ 17.56, 22.50, 22.77, 25.69, 26.25, 36.27, 39.41, 40.44, 40.71, 55.79, 55.90, 111.09, 111.54, 111.66, 120.11, 125.00, 131.03, 135.42, 146.97, 147.18, 148.68. HRMS–EI (m/z): [M]⁺ calcd for C₂₁H₂₂O₂, 316.24023; found, 316.24053. [α]D²³ +8.40 (c 0.50, CHCl₃).

The ee value (73% ee) was determined by chiral HPLC analysis of the epoxy derivative obtained by the ring closing metathesis followed by epoxydation from 4ab [CHIRALCEL® OD-3 column, 4.6 mm x 250 mm, Daicel Chemical Industries, hexane/2-propanol = 99:1, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 46.0 min and 65.7 min for R isomer and 48.2 min and 85.3 min for S isomer]. The absolute configuration of 4ab was assigned by consideration of the stereochemical pathway.

**Derivatization of 4ab.** 4ab (37.9 mg, 0.12 mmol) was dissolved in DCM (0.7 mL), and then Grubbs 2nd catalyst (3.3 mg, 0.004 mmol) was added. After 4 h stirring at 40 °C, diethyl ether was added to the mixture. The mixture was filtered through a short plug of silica gel, which was then washed with diethyl ether. After the solvent was removed under reduced pressure, flash chromatography on silica gel (0–3% EtOAc/hexane) provided the corresponding cyclization product (18.2 mg, 0.07 mmol).

To a solution of the cyclization product (18.2 mg, 0.07 mmol) in DCM (5 mL) was added mCPBA (18.1 mg, 0.105 mmol) and NaHCO₃ (17.6 mg, 0.21 mmol) at 0 °C. After being stirred at rt for 2 h, the mixture was diluted with EtOAc, washed with Na₂S₂O₃, sat. NaHCO₃ aq, water, and brine. After the solvent was removed under reduced pressure, flash chromatography on silica gel (5–10% EtOAc/hexane) provided the epoxy derivative (8.3 mg, 0.03 mmol).
(S)-2-(6-Ethyl-6-phenethyl-7-octen-1-yl)-1,3-dioxane (4bc)

The product 4hg was purified by flash chromatography on silica gel (0–2% EtOAc/hexane) followed by GPC (CHCl₃) (75% isolated yield). Colorless Oil. IR (neat) 698, 909, 998, 1143, 2851, 2929 cm⁻¹. ¹H NMR (300 MHz, CDCl₃) δ 0.79 (t, J = 7.2 Hz, 3H), 1.20–1.45 (m, 10H), 1.53–1.63 (m, 5H), 2.08 (m, 1H), 2.41–2.47 (m, 2H), 3.76 (td, J = 12.0, 2.4 Hz, 2H), 4.08–4.13 (m, 2H), 4.51 (t, J = 5.1 Hz, 1H), 4.91 (dd, J = 17.4, 1.5 Hz, 1H), 5.08 (dd, J = 11.1, 1.5 Hz, 1H), 5.64 (dd, J = 17.4, 11.1 Hz, 1H), 7.15–7.19 (m, 3H), 7.25–7.30 (m, 2H). ¹³C NMR (100.5 MHz, CDCl₃) δ 7.83, 23.26, 24.01, 25.85, 28.43, 30.12, 30.35, 35.29, 35.64, 38.26, 42.12, 66.90, 102.39, 112.68, 125.52, 128.29 (2C), 143.45, 146.63. HRMS–EI (m/z): [M]⁺ calcd for C₂₂H₃₄O₂, 330.25588; found, 330.25466. [α]D²⁶ −5.63 (c 0.48, CHCl₃).

The ee value (81% ee) was determined by chiral HPLC analysis of the aldehyde derivative obtained by the ozonolysis followed by reduction with Me₂S from 4bc [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/CHIRALCEL® OD-H column, 4.6 mm × 250 mm/CHIRALCEL® OD-H column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 96:4, 0.7 mL/min, 40 °C, 220 nm UV detector, retention time = 37.4 min for S isomer and 42.5 min for R isomer] (4bc was converted to the corresponding aldehyde according to the procedure for the derivatization of 4ba). The absolute configuration of 4bc was assigned by consideration of the stereochemical pathway.

(S)-2-(6-Phenethyl-6-vinlnonyl)-1,3-dioxane (4bd)

The product 4bd was purified by flash chromatography on silica gel (0–2% EtOAc/hexane) followed by GPC (CHCl₃) (67% isolated yield). Colorless Oil. IR (neat) 698, 908, 998, 1144,
2850, 2929 cm\(^{-1}\). \(^1\)H NMR (300 MHz, CDCl\(_3\)) \(\delta\) 0.89 (t, \(J = 6.9\) Hz, 3H), 1.19–1.47 (m, 12H), 1.53–1.62 (m, 5H), 2.04 (m, 1H), 2.41–2.47 (m, 2H), 3.76 (t, \(J = 12.0\) Hz, 2H), 4.08–4.13 (m, 2H), 4.51 (t, \(J = 5.1\) Hz, 1H), 4.90 (d, \(J = 17.4\) Hz, 1H), 5.06 (d, \(J = 11.1\) Hz, 1H), 5.65 (dd, \(J = 17.4, 11.1\) Hz, 1H), 7.14–7.18 (m, 3H), 7.24–7.29 (m, 2H).

\(^{13}\)C NMR (100.5 MHz, CDCl\(_3\)) \(\delta\) 14.92, 16.64, 23.31, 24.03, 25.86, 30.14, 30.36, 35.30, 36.22, 38.72, 38.79, 42.08, 66.91, 102.40, 112.40, 125.52, 128.29 (2C), 143.44, 146.93. HRMS–EI (m/z): [M]\(^+\) calcd for C\(_{23}\)H\(_{36}\)O\(_2\), 344.27153; found, 344.27039.

The ee value (71% ee) was determined by chiral HPLC analysis of the aldehyde derivative obtained by the ozonolysis followed by reduction with Me\(_2\)S from 4bd [CHIRALCEL® OD-3 column, 4.6 mm \(\times\) 250 mm/CHIRALCEL® OD-H column, 4.6 mm \(\times\) 250 mm/CHIRALCEL® OD-H column, 4.6 mm \(\times\) 250 mm, Daicel Chemical Industries, hexane/2-propanol = 96:4, 0.7 mL/min, 40 °C, 220 nm UV detector, retention time = 29.9 min for S isomer and 32.6 min for R isomer] (4bd was converted to the corresponding aldehyde according to the procedure for the derivatization of 4ba). The absolute configuration of 4bd was assigned by consideration of the stereochemical pathway.

(R)-DTBM-TunePHOS (L1)

L1 was prepared according to the literature procedure.\(^{21}\) White solid. HRMS–ESI (m/z): [M+H]\(^+\) calcd for C\(_{77}\)H\(_{109}\)O\(_6\)P\(_2\), 1191.7706; found, 1191.76939. [\(\alpha\)]\(_D\)\(^{23}\) = 85.69 (c 0.53, CHCl\(_3\)).

(3) For a review on transition metal catalyzed allylic substitutions with organoboron compounds, see: Pigge, F. C. *Synthesis* **2010**, *42*, 1745–1762.

For Tables 1, 2 and eq 2, small amounts of dechlorinated compounds that stemmed solely from the allyl chloride (3) were detected in the crude materials after removal of the catalyst.

The absolute configuration of 4ha was determined by transforming it to a known compound. See Supporting Information for details. Absolute configurations of 4aa and the other products listed in Table 2 were assigned by consideration of the stereochemical pathway.

Rapid and quantitative formation of a tetravalent borate (2a') was confirmed by 11B NMR spectroscopy. Treatment of 2a with EtOK in THF/DCM (1:3) at 25 °C for 10 min caused a complete disappearance of the signal for 2a (δ 69.6, rt), and a new signal appeared at the higher magnetic field (δ 3.1), which was assigned to 2a' (ref 6a). Subsequent mixing of the borate with one equiv of CuOTf·(toluene)0.5/(R)-DTBM-MeO-BIPHEP (L4) at 25 °C for 15 min formed 9-BBN-OEt (δ 55.6, rt). See Supporting Information for details of the NMR studies.

EtOK was optimal among the bases screened. The use of MeOK instead of EtOK under the conditions for Table 1, entry 4 decreased the product yield (14% yield) with the regioselectivity and enantioselectivity unchanged (γ/α >20:1, 83% ee). The use of t-BuOK resulted in no reaction.

Chapter 2
Copper-Catalyzed Enantioselective Intramolecular Alkylboron

Allylic Alkylation

A reductive C–C-bond-forming cyclization of vinyl-terminated allyl chlorides via alkene hydroboration with 9-BBN-H followed by Cu-catalyzed asymmetric intramolecular allylic alkylation with a new chiral phosphoramidite ligand produced six-membered ring compounds with a tertiary or quaternary stereogenic center in the ring with high enantioselectivity.
Introduction

Transition metal catalyzed enantioselective allylic substitution of organometallic reagents is one of the most powerful and versatile methods for asymmetric C–C bond formation.\(^1\) Recently, allylic substitution reactions utilizing organoboron compounds have made a remarkable advance, allowing the expansion of substrate scopes with great functional group compatibilities.\(^2\)-\(^6\) Although the applicable organoboron reagents had been limited to aryl-, alkenyl-, allyl-, propargyl-, and allenylboron derivatives, more recently Sawamura and Ohmiya introduced protocols for using alkyl-9-BBN reagents for stereoselective \(\gamma\)-selective allylic alkylation.\(^7\)-\(^8\)

**Scheme 1.** Copper-Catalyzed Enantioselective Inter- and Intramolecular Allylic Substitution Reactions.

In the reported intermolecular copper-catalyzed enantioselective allylic alkylation reactions with alkyl-9-BBN reagents, Sawamura and Ohmiya identified \(C_2\)-symmetric bisphosphine ligands with axially chiral biaryl backbone and bulky \(P\)-aryl substituents to be suitable for producing highly active and enantioselective copper catalysts (Scheme 1a).\(^8\) The reactions afforded enantioenriched chiral terminal alkenes containing tertiary or quaternary carbon stereogenic centers branched with \(sp^3\)-alkyl groups at the allylic position. The wide availability of alkylboranes via alkene hydroboration and their great functional group compatibility are attractive features of these transformations. Based on this knowledge, the author sought to develop a method for synthesizing cyclic compounds with a stereogenic carbon center in a ring through intramolecular enantioselective reductive allylic alkylation of bifunctional molecules with a terminal alkene and an allyl (psheudo)halide moiety with a possibility for coexistence of the trialkylborane and the electrophilic allyl moiety in mind.\(^10\)
This chapter describes enantioselective reductive cyclization of allyl chlorides tethered to a terminal alkene that goes through 9-BBN hydroboration of the terminal alkene followed by copper-catalyzed enantioselective intramolecular allylic alkylation with a new chiral phosphoramidite ligand (Scheme 1b). The reaction afforded functionalized chiral six-membered ring compounds containing tertiary or quaternary carbon stereogenic centers substituted with a vinyl group with high enantioselectivities.

Results and Discussion

Discovery of the reaction and screening of conditions

An initial screening of chiral ligand for the enantioselective copper-catalyzed cyclization was conducted with alkylborane \((Z)-2a\), which was prepared by hydroboration of \((Z)-1a\), in the presence of \([\text{CuOTf·(toluene)}]_{0.5}\) (10 mol%) and KOMe in toluene at 25 °C (Table 1). \((R)\)-DTBMSegphos (L1), which exhibited high performance in the intermolecular reaction, induced low enantioselectivity (74% yield, 43% ee) (entry 1). On the other hand, the screening has revealed that some phosphoramidite-type chiral monodentate phosphine ligand are more suitable than the bidentate phosphine ligands in terms of both catalytic activity and enantioselectivity. The reaction proceeded most efficiently (82% yield, 85% ee) in the presence of a newly synthesized phosphoramidite ligand (L2), which consists of a \((S)\)-H8-binaphthol backbone and two \(N-(R)-1-(\alpha\text{-naphthyl})\text{ethyl}\) groups (entry 2). Changing the \(\alpha\text{-naphthyl}\) groups of L2 to sterically less hindered phenyl groups slightly reduced the product yield and enantioselectivity (78% yield, 80% ee) (entry 3). While a ligand (L4) with an achiral biphenol backbone instead of the \((S)\)-H8-binaphthol backbone of L2 retained some enantioselectivity (30% yield, 39% ee) (entry 4), replacement of the \(N-(R)-1-(\alpha\text{-naphthyl})\text{ethyl}\) groups of L2 with N-methyl groups (L5) resulted in complete loss of enantioselectivity (entry 5). Thus, the chiral amine moiety is more important than the diol moiety for the enantiocontrol.

Using L2 as the optimal chiral ligand, effects of solvents were examined (Table 1, entries 6–9). Mesitylene gave better product yield and enantioselectivity (85% yield and 90% ee) than toluene (entry 6). THF inhibited the reaction almost completely (entry 7). In contrast, cyclopentyl methyl ether (CPME) was suitable for the reaction (70% yield and 87% ee), suggesting that weaker coordination ability or lower polarity of solvent is favorable (entry 8). The highest...
enantioselectivity (91% ee) was observed with a mixed solvent system mesitylene/methyl tert-butyl ether (MTBE) (1:3) (entry 9).

The reaction with \((E)-1\text{a}\) under the optimal conditions (Table 1, entry 9) provided \((R)-3\text{a}\), the antipode of the product from \((Z)-1\text{a}\), with 87% ee in 70% yield (Scheme 2). Thus, \(Z\)-configuration is more favorable than \(E\)-configuration in the allyl chloride moiety, and the substitution pattern at the position \(\beta\) to the chlorine atom is more important than that at the \(\gamma\)-position for enantiodiscrimination by the catalyst.

**Scheme 2.** Cu-catalyzed Enantioselective Intramolecular Allylic Substitution of \((E)-1\text{a}\).

Substrates

Other substrates with different linkers between the vinyl group and allyl chloride moiety were subjected to the hydroboration-cyclization protocol under the same conditions. The results are summarized in Table 2. This study demonstrates good functional group tolerance of the protocol. For example, the reaction of diethyl malonate-tethered substrate \(1\text{b}\) afforded the corresponding product \(3\text{b}\) in good enantioselectivity (85% ee), albeit in moderate yield (50% yield) (entry 1). The reaction of sulfone derivative \(1\text{c}\) gave \(3\text{c}\) with 89% ee (entry 2). The protocol is applicable for the synthesis of a chiral \(N\)-tritylpiperidine derivative (3d, 90% ee) through the reaction of the corresponding \(N\)-tethered substrate \(1\text{d}\) (entry 3). The five-membered ring formation with a 1,1-dibenzylmethylene tethered substrate \(1\text{e}\) gave the expected cyclic product (3e) in low yield and low enantioselectivity (34% yield, 33% ee) (entry 4). A restricted coordination geometry of the alkene may be unfavorable for enantioselection by the catalyst.

Considerations for reaction pathways

A possible reaction pathway for the intramolecular allylic alkylation catalyzed by the CuX-L2 system (A, CuX-P, X = Cl or OMe) is proposed in Figure 1. Similarly to the intermolecular reaction reported previously, this intramolecular reaction should be initiated by transmetalation between the copper(I) complex A and borate B, which is formed from 2 and KOMe, to produce a neutral alkylcopper(I) complex (C) coordinated with the monophosphine L2 (P) and the alkene moiety of the allylic substrate. The intramolecular 2-coordinate of the alkene in C should be more feasible than the coordination of alkene in the intermolecular allylic alkylation. This difference in alkene coordination may be a cause of the experimentally observed difference in preferred denticity for phosphine coordination. Next, the alkylcopper(I) intermediate C undergoes C–Cu addition across the bound C–C double bond, forming E. Then, Cu–Cl elimination affords 3 and regenerates A for the next catalytic cycle.

Figure 1. A possible reaction pathway for the copper-catalyzed intramolecular allylic alkylation of an alkyl-9-BBN derivative.
**Conclusion**

In summary, the author developed the reductive cyclization reaction of allyl chlorides tethered to a terminal alkene via alkene hydroboration followed by in-situ enantioselective intramolecular allylic alkylation of organoboron intermediates catalyzed by a copper(I)-phosphoramidite system. The reaction afforded functionalized chiral cyclic compounds bearing enantioenriched tertiary or quaternary carbon stereogenic centers.

**Experimental Section**

**Instrumentation and Chemicals**

NMR spectra were recorded on a JEOL ECX-400, operating at 400 MHz for $^1$H NMR, 100.5 MHz for $^{13}$C NMR and 168 MHz for $^{31}$P NMR. Chemical shift values for $^1$H and $^{13}$C are referenced to Me$_4$Si and the residual solvent resonances, respectively, while H$_3$PO$_4$ was used as the reference for $^{31}$P NMR. Chemical shifts are reported in δ ppm. Mass spectra were obtained with Thermo Fisher Scientific Exactive, JEOL JMS-T100LP or JEOL JMS-700TZ at the Instrumental Analysis Division, Global Facility Center, Creative Research Institution, Hokkaido University. HPLC analyses were conducted on a HITACHI ELITE LaChrom system with a HITACHI L-2455 diode array detector or a HITACHI Chromaster with a HITACHI 5430 diode array detector. Optical rotations were measured on a JASCO P-2200. TLC analyses were performed on commercial glass plates bearing 0.25-mm layer of Merck Silica gel 60F$_{254}$. Silica gel (Kanto Chemical Co., Silica gel 60 N, spherical, neutral) was used for column chromatography. Gel permeation chromatography (GPC) was performed by LC-908 (Japan Analytical Industry Ltd., two in-line JAIGEL-2H, CHCl$_3$, 3.5 mL/min, UV and RI detectors). Melting points were measured on a Yanaco MP-500D apparatus.

All reactions were carried out under nitrogen or argon atmosphere. Materials were obtained from commercial suppliers or prepared according to standard procedures unless otherwise noted. 9-Borabicyclo[3,3,1]nonane dimer (9-BBN-H)$_2$, CuOTf·(toluene)$_{0.5}$, KOMe, were purchased from Aldrich Chemical Co., stored under nitrogen, and used as it is. (R)-DTBM-SEGPHOS was purchased from Strem Chemicals Inc., stored under nitrogen, and used as it is. Toluene, mesitylene, CPME and MTBE were purchased from Kanto Chemical Co., stored over 4Å molecular sieves under nitrogen. THF was purchased from Kanto Chemical Co., stored over 5Å molecular sieves under nitrogen.
Preparation of (Z)-allyl chloride 1a and (E)-allyl chloride 1a and 4a (Scheme 4)

(Z)-1a, (E)-1a and (E)-4a were prepared through same procedure. The preparation of (Z)-1a is representative (Scheme 4). To a suspension of NaH (55% in mineral oil, 785.1 mg, 18.0 mmol) in DMF (20 mL) at 0 °C was added a solution of 6 (3.0 g, 15.0 mmol) in DMF (10 mL). After stirring for 30 min, allylbromide derivative 7 (3.52 g, 15.0 mmol) was added. After being stirred at room temperature for 12 h, the reaction was quenched with aqueous saturated NH₄Cl solution (15 mL) and extracted with EtOAc (30 mL × 3). The organic layers were combined and dried over MgSO₄. The filtrate was concentrated in vacuo, and was used for next step without further purification.

8 was added to a suspension of LiAlH₄ (1.19 g, 30 mmol) in DCM (15 mL) at 0 °C. The mixture was stirred at this temperature for 2 h. After quenching with NaOH aq, the mixture was filtered and concentrated. The corresponding diol product 9 was used for next step without further purification.

The diol compound 9 was added dropwise to a suspension of NaH (55 wt.%, 1.56 g, 36.0 mmol) in THF (20 mL) at 0 °C. The mixture was stirred at 0 °C for 30 min. Subsequently, BnBr (4.7 mL, 39 mmol) was added, and the reaction was stirred for 12 h. After quenching with sat. NH₄Cl aq., the mixture was extracted with Et₂O. The organic layer was washed with brine, dried over MgSO₄, filtered, and concentrated. The residue was used for next step without further purification.

A solution of benzyl ether 10 and p-TsOH (57 mg, 0.3 mmol) in MeOH (15 mL) was stirred at room temperature for 2 h. H₂O was added to quench the reaction. The resulting mixture was extracted with CH₂Cl₂ (50 mL × 3). The combined organic phase was washed with brine, dried over MgSO₄ and filtered. After removal of solvent, the crude compound was purified by flash chromatography on silica gel (5–20% EtOAc/hexane) to give allyl alcohol 11 (3.57 g, 9.8 mmol) in 65% yield (4 steps).

To a suspension of allyl alcohol 11 (1.10 g, 3.0 mmol) in DMF (9.0 mL) at 0 °C, LiCl (1.14 g, 27.0 mmol), and collidine (1.6 mL, 12.0 mmol) in DMF (9 mL) were added MsCl (580.5 µL, 7.5 mmol). The mixture was stirred at this temperature for 15 min before the temperature was allowed to rise to room temperature. After being stirred at room temperature for 30 min, the reaction was quenched with aqueous saturated NH₄Cl solution (15 mL) and extracted with EtOAc (18 mL × 3). The organic layers were combined and dried over MgSO₄. The filtrate was concentrated in vacuo, and the residue was purified by flash column chromatography on silica gel (0–1% EtOAc/hexane) to yield 981.6 mg (2.6 mmol, 85%) of 1a as a colorless oil.

Preparation of (Z)-allyl chlorides 1b (Scheme 5).

To a suspension of NaH (55% in mineral oil, 287.9 mg, 6.6 mmol) in DMF (8 mL) at 0 °C was added a solution of diethyl allylmalonate 6 (1.2 mL, 6.0 mmol) in DMF (4 mL). After stirring for 30 min, cis-1,4-dichloro-2-butene (1.2 mL, 12 mmol) was added. After being stirred at room temperature for 12 h, the reaction was quenched with aqueous saturated NH₄Cl solution (6 mL) and extracted with EtOAc (12 mL × 3). The organic layers were combined and dried over MgSO₄. The filtrate was concentrated in vacuo, and the residue was purified by flash column chromatography on silica gel (1–2% EtOAc/hexane) to yield 1.39 g (4.8 mmol, 80%) of 1b as a colorless oil.

Scheme 5. Preparation of (Z)-1b

Preparation of (Z)-allyl chlorides 1c (Scheme 6).

To a suspension of NaH (55% in mineral oil, 287.9 mg, 6.6 mmol) in DMF (8 mL) at 0 °C was added a solution of bisphenylsulfonylmethane 12 (1.78 g, 6.0 mmol) in DMF (4 mL). After stirring for 30 min, allylbromide (533 µL, 6.3 mmol) was added. After being stirred at room temperature for 12 h, the reaction was quenched with aqueous saturated NH₄Cl solution (7 mL) and extracted with EtOAc (12 mL × 3). The organic layers were combined and dried over MgSO₄. The filtrate was concentrated in vacuo, and the residue was purified by flash column chromatography on silica gel (15–30% EtOAc/hexane) to yield 260 mg (5.0 mmol, 83%, 2 steps)
of allyl bisphenylsulfonylmethane 13 as a white solid.

To a suspension of NaH (55% in mineral oil, 96.0 mg, 2.2 mmol) in DMF (6 mL) at 0 °C was added a solution of 13 (672.8 mg, 2.0 mmol) in DMF (2 mL). After stirring for 30 min, cis-1,4-dichloro-2-butene (420 µL, 4.0 mmol) was added. After being stirred at room temperature for 12 h, the reaction was quenched with aqueous saturated NH₄Cl solution (6 mL) and extracted with EtOAc (8 mL × 3). The organic layers were combined and dried over MgSO₄. The filtrate was concentrated in vacuo, and the residue was purified by flash column chromatography on silica gel (5–20% EtOAc/hexane) and GPC to yield 509.9 mg (1.2 mmol, 60%) of 1c as a white solid.

Scheme 6. Preparation of (Z)-1c

Preparation of (Z)-allyl chlorides 1d (Scheme 7).

To a stirred suspension of K₂CO₃ (608.1 mg, 4.4 mmol) in allylamine (2.1 mL, 28.0 mmol) at room temperature, 14 (1.06 g, 4.0 mmol) was added dropwise over 45 min. After stirring at room temperature for 12 h the reaction mixture was filtered through a pad of Celite followed by evaporation of excess allylamine in vacuo. The residue was used for next step without further purification.

A solution of the corresponding crude amine 15 (2.0 mmol) in DCM (1 mL) was added to a solution of trityl chloride (613.3 mg, 2.2 mmol), Et₃N (502 µL, 3.6 mmol) and DMAP (9.8 mg, 0.08 mmol) at room temperature and the mixture was stirred for 12 h. The reaction was then quenched with H₂O (1 mL) and extracted with EtOAc (15 mL × 3) and the combined organic phases were washed with brine (5 mL) and dried over Na₂SO₄. After evaporation of the solvents, the resulting residue was purified by flash chromatography on silica gel (0–2% EtOAc/hexane) to give 16 (532.1 mg, 1.1 mmol) in 55% yield (2 steps).

To a solution of 16 (532.1 mg, 1.1 mmol) in THF (5.5 mL) was added TBAF (1.7 mL of 1.0 M in THF solution, 1.7 mmol) at 0 °C. The mixture was stirred for 1 h. The reaction was then quenched with H₂O (5 mL) and extracted with EtOAc (15 mL × 3) and the combined organic phases were washed with brine (5 mL) and dried over Na₂SO₄. After evaporation of the solvents, the resulting residue was purified by flash chromatography on silica gel (5–20% EtOAc/hexane) to give allyl alcohol 17.
To a suspension of 17 (168 mg, 0.75 mmol) in DMF (5 mL) at 0 °C, LiCl (500 mg, 1.18 mmol), and collidine (500 µL, 547 mg, 4.5 mmol) in DMF (5 mL) were added MsCl (250 mL, 170 mg, 1.5 mmol). The mixture was stirred at this temperature for 15 min before the temperature was allowed to rise to room temperature. After being stirred at room temperature for 30 min, the reaction was quenched with aqueous saturated NH₄Cl solution (3 mL) and extracted with EtOAc (4 mL × 3). The organic layers were combined and dried over MgSO₄. The filtrate was concentrated in vacuo, and the residue was purified by flash column chromatography on silica gel (0–2% EtOAc/hexane) to yield 244 mg (0.63 mmol, 84%) of 1d as a pale yellow oil.

Scheme 7. Preparation of (Z)-1d

Preparation of (Z)-allyl chlorides 1e (Scheme 8).

A suspension of diethyl dibenzylmalonate 18 (4.45 g, 13.0 mmol) and LiCl (3.86 g, 91.0 mmol) in DMSO (38 mL) was stirred at 170 °C for 6 h. The reaction mixture was allowed to stirred at room temperature, treated with water (1.3 mL), stirred for another 1 h, diluted with EtOAc (30 mL) and extracted with EtOAc (30 mL × 3). The organic layers were combined and dried over MgSO₄. The filtrate was concentrated in vacuo, and the residue was purified by flash column chromatography on silica gel (0–2% EtOAc/hexane) to yield 2.44 g (9.1 mmol, 70%) of 2-benzyl-3-phenylpropanoate 19 as pale yellow oil.

To a solution of 19 (1.74 g, 6.5 mmol) in dry THF (13 mL), LDA (7.8 mmol) was added at −78 °C. The resultant solution was stirred at −78 °C for 15 min and then 14 (2.07 g, 7.8 mmol) in THF (10 mL) was added. The mixture was stirred at this temperature for 6 h. The reaction was quenched with aqueous saturated NH₄Cl solution (6 mL) and extracted with EtOAc (13 mL × 3). The organic layers were combined and dried over MgSO₄. The filtrate was concentrated in vacuo, and the residue was purified by flash column chromatography on silica gel (0–3% EtOAc/hexane)
to yield 2.27 g (5.0 mmol, 77%) of 20 as a pale yellow oil.

20 (2.27 g, 5.0 mmol) was added to a suspension of LiAlH₄ (247.5 mg, 6.0 mmol) in Et₂O (50 mL) at 0 °C. The mixture was allowed to stirred at room temperature for 2 h. After quenching with NaOH aq at 0 °C, the mixture was filtered and concentrated. The crude primary alcohol 21 was used for next step without further purification.

Powdered 4 Å molecular sieves and NMO (878.6 mg, 7.5 mmol) were added to a solution of the crude primary alcohol 21 in DCM (6 mL). The resultant solution was stirred at room temperature for 10 min and then TPAP (88.0 mg, 0.25 mmol) in DCM (3 mL) was added at 0 °C. The mixture was allowed to warm to room temperature and stirred for 1 h, then loaded onto silica and eluted using hexane until all aldehyde had been collected. The crude aldehyde 22 was used for next step without further purification.

Methyltriphenylphosphonium bromide (3.21 g, 9.0 mmol) was suspended in THF (6 mL) and cooled to 0 °C. KOtBu (841.6 mg, 7.6 mmol) was added in one portion, and the reaction mixture was stirred at 0 °C for 30 min. The crude aldehyde 22 was dissolved in THF (4 mL) and added to the ylide. After the mixture was stirred for room temperature for 12 h, hexane (25 mL) was added, and the resulting thick suspension was filtered through Celite. The filter cake was washed with Et₂O and the solution concentrated then purified by flash column chromatography on silica gel (0–1% EtOAc/hexane) to yield 1.63 g (4.0 mmol, 80% in 3 steps) of 23 as pale yellow oil.

To a solution of 23 (813.4 mg, 2.0 mmol) in THF (10 mL) was added TBAF (3.0 mL of 1.0 M in THF solution, 3.0 mmol) at 0 °C. The mixture was stirred for 1 h. The reaction was then quenched with H₂O (5 mL) and extracted with EtOAc (10 mL × 3) and the combined organic phases were washed with brine (5 mL) and dried over MgSO₄. After evaporation of the solvents, the resulting residue was purified by flash chromatography on silica gel (5–20% EtOAc/hexane) to give allyl alcohol 24 (467.9 mg, 1.6 mmol) in 80% yield.

To a suspension of 24 (292.4 mg, 1.0 mmol) in DMF (3 mL) at 0 °C, LiCl (381.5 mg, 9.0 mmol), and collidine (530 µL, 4.0 mmol) in DMF (3 mL) were added MsCl (154.8 µL, 2.0 mmol). The mixture was stirred at this temperature for 15 min before the temperature was allowed to rise to room temperature. After being stirred at room temperature for 30 min, the reaction was quenched with aqueous saturated NH₄Cl solution (5 mL) and extracted with EtOAc (7 mL × 3). The organic layers were combined and dried over MgSO₄. The filtrate was concentrated in vacuo, and the residue was purified by flash column chromatography on silica gel (0–1% EtOAc/hexane) to yield 217.6 mg (0.7 mmol, 70%) of 1e as a colorless oil.

The ee value (87% ee) was determined by chiral HPLC analysis of 3a [CHIRALCEL\(^®\) OD-3 column, 4.6 mm \(\times\) 250 mm/OD-H column, 4.6 mm \(\times\) 250 mm, Daicel Chemical Industries, hexane, 0.7 mL/min, 40 °C, 220 nm UV detector, retention time = 30.2 min for \(S\) isomer and 31.5 min for
The absolute configuration of 3a was assigned by consideration of the stereochemical pathway.

**(S)-Diethyl-3-vinylcyclohexane-1,1-dicarboxylate (3b)**

![Chemical structure of (S)-3b]

The product 3b was purified by flash chromatography on silica gel (0–2% EtOAc/hexane) and GPC (13.2 mg, 0.05 mmol, 50% isolated yield from (Z)-1b). Pale Yellow Oil. **IR** (neat) 698, 911, 1066, 1096, 1141, 1242, 1310, 1451, 1640, 1728, 2857, 2935 cm⁻¹. **¹H NMR** (400 MHz, CDCl₃) δ 1.21–1.29 (m, 6H), 1.38–1.48 (m, 2H), 1.53–1.62 (m, 2H), 1.71–1.77 (m, 2H), 2.16 (m, 1H), 2.32–2.43 (m, 2H), 4.15–4.22 (m, 4H), 4.94 (d, J = 10.0 Hz, 1H), 5.00 (d, J = 17.6 Hz, 1H), 5.74 (ddd, J = 17.6, 10.0, 6.4 Hz, 1H). **¹³C NMR** (100 MHz, CDCl₃) δ 14.0, 14.1, 22.3, 30.8, 31.1, 36.6, 37.6, 55.0, 61.1, 61.3, 112.8, 143.1, 171.1, 172.4. **HRMS–EI (m/z):** [M]+ calcld for C₁₄H₂₂O₄, 254.15181; found, 254.15236. [α]D²⁵ −1.92 (c 0.35, CHCl₃). The ee value (85% ee) was determined by chiral HPLC analysis of p-nitrobenzoate derivertive obtained by the ozonolysis, reduction with NaBH₄ followed by benzylation from 3b [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/OD-3 column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 99:1, 0.8 mL/min, 40 °C, 220 nm UV detector, retention time = 46.8 min for S isomer and 49.2 min for R isomer]. The absolute configuration of 3b was assigned by consideration of the stereochemical pathway.

**Derivatization of 3b.**

Ozone was bubbled into a solution of 3b (7.6 mg, 0.03 mmol) in MeOH/diethyl ether (1:10, 5.0 mL) at −78 °C. After the starting material was completely disappeared (monitored by TLC), NaBH₄ (11.3 mg, 0.3 mmol) was added and the mixture was allowed to warm to room temperature and it was further stirred at the room temperature for 1 h. The mixture was quenched with water. The aqueous layer was extracted with EtOAc (three times). The combined organic layer was washed with water and brine, and then was dried and concentrated. The crude alcohol was used for next step without further purification.

To a solution of the corresponding alcohol in 300 µL of dry DCM were successively added DMAP (6.7 mg, 0.06 mmol) and 4-nitrobenzoyl chloride (6.7 mg, 0.036 mmol). After being stirred for 1 h at room temperature, the mixture was filtered through a short plug of silica gel, which was then washed with diethyl ether. The solvent was removed and the resulting residue was purified by flash chromatography on silica gel (2–5% EtOAc/hexane) provided p-nitrobenzoate derivative (6.5 mg, 0.016 mmol) in 53% yield (2 steps).
(S)-(3-Vinylcyclohexane-1,1-disulfonyle) dibenzene (3c)

The product 3c was purified by flash chromatography on silica gel (3–7% EtOAc/hexane) and GPC (16.6 mg, 0.04 mmol, 40% isolated yield from (Z)-1c). Pale Yellow Oil. IR (neat) 685, 726, 921, 1075, 1142, 1305, 1446, 1583, 1640, 2921 cm⁻¹. ¹H NMR (400 MHz, CDCl₃) δ 1.09 (m, 1H), 1.77–1.88 (m, 2H), 2.05 (m, 1H), 2.02–2.32 (m, 4H), 2.91 (m, 1H), 4.98 (d, J = 10.4 Hz, 1H), 5.03 (d, J = 16.8 Hz, 1H). IR (neat) 685, 726, 921, 1075, 1142, 1305, 1446, 1583, 1640, 2921 cm⁻¹. ¹H NMR (400 MHz, CDCl₃) δ 1.09 (m, 1H), 1.77–1.88 (m, 2H), 2.05 (m, 1H), 2.02–2.32 (m, 4H), 2.91 (m, 1H), 4.98 (d, J = 10.4 Hz, 1H), 5.03 (d, J = 16.8 Hz, 1H), 5.67 (ddd, J = 16.8, 10.4, 6.8 Hz, 1H), 7.56–7.61 (m, 4H), 7.67–7.73 (m, 2H), 8.01 (d, J = 7.2 Hz, 2H), 8.09 (d, J = 7.2 Hz, 2H). ¹³C NMR (100 MHz, CDCl₃) δ 21.2, 26.0, 29.9, 31.5, 36.3, 88.3, 114.1, 128.5, 131.1, 131.6, 134.3, 134.5, 136.2, 136.7, 142.1. HRMS–ESI (m/z): [M+Na]+ calcld for C₂₀H₂₂O₄Na₂S₂, 413.08518; found, 413.08517. [α]D₂⁵ −16.67 (c 0.31, CHCl₃). The ee value (89% ee) was determined by chiral HPLC analysis of 3c [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 90:10, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 17.9 min for R isomer and 19.1 min for S isomer]. The absolute configuration of 3c was assigned by consideration of the stereochemical pathway.

(R)-1-Trityl-3-vinylpiperidine (3d)

The product 3d was purified by flash chromatography on silica gel (0–1% EtOAc/hexane) (21.2 mg, 0.06 mmol, 60% isolated yield from (Z)-1d). White solid. M.p. 74.2–75.8 °C. IR (neat) 697, 758, 1018, 1215, 1447, 1586, 1639, 1735, 2852, 2924, 3059 cm⁻¹. ¹H NMR (400 MHz, CDCl₃) δ 0.86–1.41 (br, 3H), 1.66–1.80 (br, 3H), 2.52 (br, 1H), 3.03–3.10 (br, 2H), 4.87–4.98 (br, 2H), 5.64 (br, 1H), 7.13–7.45 (br, 15H). ¹³C NMR (100 MHz, CDCl₃) δ 30.7, 41.1, 48.9, 54.3 (×2C), 77.5, 113.3, 125.8, 127.3, 129.3 (br, ×2C), 141.8. HRMS–ESI (m/z): [M]+ calcld for C₂₆H₂₇N, 353.21435; found, 353.21356. [α]D₂⁶ −21.89 (c 1.21, CHCl₃). The ee value (90% ee) was determined by chiral
HPLC analysis of 3e [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/OD-3 column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane, 0.3 mL/min, 40 °C, 250 nm UV detector, retention time = 56.0 min for R isomer and 59.4 min for S isomer]. The absolute configuration of 3d was determined by optical rotation of the alcohol derivative. \([\alpha]_D^{24} +17.77 \text{ (c 0.98, CHCl}_3\text{) .} \) \(\text{[lit}^{21}, (S)\text{ isomer, >99% ee, } [\alpha]_D^{32} -16.2 \text{ (c 0.9, CHCl}_3]\). \)

**Derivatization of 3d.**

3d (42.4 mg, 0.12 mmol) was dissolved in a mixture of chloroform (120 µL) and methanol (120 µL) and cooled to 0 °C in an ice-bath. TFA (120 µL) was added dropwise and the reaction mixture was stirred at 0 °C 1 h. The solvents were removed under reduced pressure at 0 °C and the resulting solid residue was azeotroped five times with diethyl ether (three times) at 0 °C and partitioned between diethyl ether (1 mL) and water (2 mL). The organic layer was washed with water (two times) and the combined aqueous fractions were basified with NaHCO₃ (50.4 mg, 0.6 mmol). The aqueous fractions were diluted with ethyl acetate (3 mL) and the mixture was cooled to 0 °C. Benzyl chloroformate (14.7 µL, 0.12 mmol) was added and the reaction mixture was stirred vigorously at room temperature for 6 h. The layers were separated and the aqueous layer was washed with ethyl acetate (3 mL). The combined organic fractions were washed with brine, then dried over Na₂SO₄. After evaporation of the solvents, the resulting residue was purified by flash chromatography on silica gel (2–5% EtOAc/hexane) to give the corresponding N-benzyloxycarbonyl piperidine derivative (20.6 mg, 0.084 mmol) in 70% yield.

N-benzyloxycarbonyl piperidine (19.6 mg, 0.080 mmol) was added to a solution of 9-BBN dimer (11.7 mg, 0.048 mmol) in THF (170 µL). The reaction mixture was stirred at 60 °C for 1 h. The mixture was cooled to 0 °C and treated cautiously with a mixture of THF (100 µL), 30 % hydrogen peroxide (32.6 µL) and aqueous sodium hydroxide (320 µL of a 1 M solution), stirred at room temperature for 1 h. Na₂S₂O₃aq was added, the layers were separated, and the aqueous phase was extracted with CH₂Cl₂ (three times). The combined organic layers were washed with brine, dried over Na₂SO₄, and concentrated in vacuo to give a colorless oil that was purified by GPC to provide alcohol derivative (16.9 mg, 0.064 mmol) in 80% yield.

The ee value (33% ee) was determined by chiral HPLC analysis of alcohol derivative obtained by the hydroboration followed by oxidation from 3d [CHIRALCEL\(^{\text{R}}\) OD-3 column, 4.6 mm \(\times\) 250 mm, Daicel Chemical Industries, hexane/2-propanol = 96:4, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 22.7 min for minor isomer and 25.2 min for major isomer].

**Derivatization of 3e.**

3e (5.5 mg, 0.020 mmol) was added to a solution of 9-BBN dimer (2.9 mg, 0.012 mmol) in THF (100 µL). The reaction mixture was stirred at 60 °C for 1 h. The mixture was cooled to 0 °C and treated cautiously with a mixture of THF (50 µL), 30 % hydrogen peroxide (8.1 µL) and aqueous sodium hydroxide (80 µL of a 1 M solution), stirred at room temperature for 1 h. Na\(_2\)S\(_2\)O\(_3\)aq was added, the layers were separated, and the aqueous phase was extracted with CH\(_2\)Cl\(_2\) (three times). The combined organic layers were washed with brine, dried over Na\(_2\)SO\(_4\), and concentrated in vacuo to give a colorless oil that was purified by GPC to provide alcohol derivative (4.7 mg, 0.016 mmol) in 79% yield.

The addition of 9-BBN-H occurs at the terminal alkene exclusively.
The absolute configuration of $3d$ was determined by transforming it to a known compound. See the Supporting Information for details. Absolute configurations of $3a$ and the other products listed in Table 2 were assigned by consideration of the stereochemical pathway.

An attempt to form a seven-membered ring failed. No cyclization product was observed in a crude mixture by $^1$H NMR spectroscopy.

The absolute configuration of $5a$ was not determined.

Chapter 3

Synthesis of $\alpha$-Quaternary Formimides and Aldehydes through Copper-Catalyzed Asymmetric Three-Component Coupling Reaction of Isocyanides, Hydrosilanes, and Allylic Electrophile

A highly regio- and enantioselective Cu-catalyzed three-component coupling of isocyanides, hydrosilanes, and $\gamma,\gamma$-disubstituted allylic electrophiles was enabled by a combined use of chiral naphthol-carbene ligand, which was developed by Sawamura and Ohmiya group, as a functional Cu-supporting ligand and LiOttBu as a stoichiometric Lewis base for Si. This protocol provides simple, rapid, versatile, and reliable access to $\alpha$-quaternary formimides and aldehydes.
Introduction

Isocyanides, also called isonitriles, are chemical species isoelectronic with carbon monoxide, and their utilities in organic synthesis are remarkably diverse, having a rich history since the early 1900s (Figure 1a). Most typically, isocyanides have been employed as one-carbon reagents through their 1,1-insertion reactions into metal–element (M–E) bonds to formimidoylmetal species [M-C(=NR)-E], which exhibit characteristic reactivities in various catalytic transformations.\(^1\) Specifically, formimidoylmetal species [M-C(=NR)-H], which can be produced through isocyanide 1,1-insertion into metal–H bonds, are expected to be “formyl anion (HCO\(^-\))” equivalents (Figure 1b). In fact, about fifty years ago, Saegusa, Ito, and co-workers reported the copper-catalyzed 1,1-hydrosilylation of cyclohexyl isocyanide with trimethylsilane to yield (N-cyclohexylformimidoyl)trimethylsilane (Figure 1c). This reaction should involve silylation of catalytically generated formimidoylcopper(I) species. In this regard, Saegusa, Ito, and co-workers showed for the first time the high synthetic potential of isocyanide 1,1-insertion into a metal–H bond as a means of generating reactive “formyl anion” equivalents.\(^2\) Surprisingly, however, for a period of about a half century after this discovery, catalytic reactions involving 1,1-insertion of isocyanides into metal–H bonds were not explored except for the copper-catalyzed indole-forming reductive cyclization of a 2-alkenylaryl isocyanide reported by Chatani and co-workers in 2010 (Figure 1d),\(^3\) while it was well documented that various hydride complexes of early or middle transition metals (groups 3–5 transition metals and lanthanides) reacted with isocyanides in a stoichiometric manner to form \(\eta^1\)- or \(\eta^2\)-formimidoylmetal complexes.\(^1\) As for copper, Sadighi and co-workers recently reported the synthesis of an \(\eta^1\)-formimidoylcopper(I) complex through the stoichiometric reaction of benzyl isocyanide with isolated copper(I) hydride dimers coordinated with \(N\)-heterocyclic carbene ligands, but its reactivity was not revealed (Figure 1d).\(^4\)

This chapter describes a highly regio- and enantioselective copper-catalyzed asymmetric three-component coupling reaction of isocyanides, hydrosilanes, and γ,γ-disubstituted primary
allylic phosphates (or chlorides) yielding chiral \( \alpha \)-quaternary formimides, which were readily converted to the corresponding \( \alpha \)-quaternary aldehydes.\(^5,6\) This enantioselective copper catalysis was enabled by a combined use of authors’ original chiral naphthol-carbene ligand\(^7\) as a functional supporting ligand for Cu and Li\(\text{OTf}\) as a stoichiometric Lewis basic activator for Si (Figure 1e). The author propose the possible participation of the ionized ligand naphtholic hydroxy group for generating lithium aryloxo(formimidoyl)cuprate species.

Due to the importance of acyl anion equivalents as umpolung reagents in organic synthesis,\(^10\) numerous efforts have been made in developing metal-catalyzed enantioselective allylic alkylation reactions using this type of nucleophile. For instance, stabilized carbanions prepared from acetoxy Meldrum’s acid or malononitrile under basic conditions were employed as alkoxy carbonyl anion equivalents in the palladium and iridium catalyst systems.\(^11,12\) The palladium-catalyzed enantioselective allylic substitution with a sodium salt of 1-phenylsulfonyl-1-nitroethane as an acyl anion equivalent was developed and applied to the synthesis of hygromycin analogues.\(^13\) More recently, formaldehyde \(N,N\)-dialkylhydrazones were introduced as formyl anion equivalents in the iridium-catalyzed enantioselective kinetic resolution of racemic secondary allylic carbonates.\(^14\) However, these protocols constructed only tertiary carbon stereogenic centers. The enantioselective construction of all-carbon quaternary stereogenic centers remains highly challenging, in part due to the increased steric hindrance caused by the non-hydrogen substituents of a prochiral carbon.\(^15\)–\(^17\) Given the synthetic versatility of enantioenriched chiral \( \alpha \)-quaternary carbonyl compounds and their derivatives with transformable functional groups and the difficulty of preparing them, the development of such reactions is highly desirable.\(^18,19\) The enantioselective copper catalysis with isocyanides presented here provides simple, rapid, versatile, and reliable access to all-carbon quaternary stereogenic centers substituted with formimidoyl (or formyl) and vinyl groups, both of which can be used as handles for further transformations. It is to be noted that various \( \alpha \)-quaternary formimides or aldehydes asymmetrically branched with various alkyl and aryl groups with very high enantiomeric excesses (96–99% ee) were obtained.

**Results and discussion**

**Discovery of the reaction and screening of conditions**

In previous reports from Sawamura and Ohmiya group on the copper-catalyzed enantioselective allylic substitution reactions of prochiral primary allylic phosphates with terminal alkyne or azole pronucleophiles, they synthesized some phenol-carbene chiral ligands and found them particularly efficient for enantioselective catalysis owing to the functional roles of the phenolic hydroxyl groups.\(^7,8\) The phenol-carbene chiral ligands were also useful for copper-
catalyzed enantioselective allylic substitution with allylboronate reagents. Based on this knowledge, the author proposed that the formation of formimidoylcopper(I) species from isocyanides might cooperate in a catalytic manner with the enantioselective allylic substitution to provide a new entry to enantioenriched α-branched formimides or aldehydes (Figure 1e).

</table>
In fact, the three-component coupling reaction of Me$_2$PhSiH (1a) (0.18 mmol), cyclohexyl isocyanide (2a) (0.165 mmol) and (Z)-3-phenyl-2-buten-1-ol derivative 3a (0.15 mmol) occurred efficiently and cleanly in the presence of a stoichiometric amount of LiOrBu (0.18 mmol) and a catalytic amount of CuCl (10 mol%) and a chiral imidazolium salt (L$_1$·HBF$_4$, 10 mol%) in THF at 25 °C to produce α-quaternary N-cyclohexylformimide (S)-4aa. This hydrolytically unstable compound was transformed to the corresponding α-quaternary aldehyde (S)-5a upon purification by silica gel chromatography. The yield of the purified (S)-5a was 93% based on 3a, and its enantiomeric excess was as high as 96% (Table 1, entry 1). The γ-regioselectivity giving the γ,γ-double-branched product (4aa) over the achiral linear product (structure not shown) was exclusive (branched/linear >99:1). The enantioselectivity was further increased to 97% ee by lowering the reaction temperature to 0 °C (entry 2). The reaction in the presence of only 0.2 equiv of LiOrBu (relative to 3a), which should be consumed as a Brønsted base to form an oxy anion form of the L$_1$ ligand (L$_1$–H) (10 mol%), under otherwise identical conditions resulted in no reaction (entry 3). The stoichiometric amount of LiOrBu (1.0 eq to 3a) seems to act as a Lewis basic activator for Si species in the copper catalysis (see Fig. 2). As for the allylic substrate, the corresponding (Z)-
allyl chloride and carbonates were not suitable due to their instability.

Other chiral carbene ligands bearing a naphthol or phenol group were less effective (Table 1, entries 4–6).\textsuperscript{7–9} Thus, replacing the N-2,4-dicyclohexyl-6-methylphenyl of L\textsubscript{1} with a N-mesityl group \[\text{(S,S)-L2}\] decreased the enantioselectivity to a moderate level (72% ee) (entry 4). The change of the naphthol group of L\textsubscript{1} to a phenol group \[\text{(S,S)-L3}\] also reduced the enantioselectivity (81%) (entry 5). The combination of phenol and N-mesityl groups \[\text{(S,S)-L4}\] resulted in significant reductions in product yield (22%) and enantioselectivity (32%) (entry 6).

The use of phenol- or naphthol-carbenes was essential not only for the enantiocontrol but also for the catalytic activity (Table 1, entries 7–10). No reaction occurred with O-methyl-protected ligand L\textsubscript{5} (entry 7). Thus, the OH group in L\textsubscript{1} was essential. The ring-unsaturated C\textsubscript{2}-symmetric carbene ligand (L\textsubscript{6}) having 1-(mesityl)ethyl groups at both nitrogen atoms gave nearly racemic product with low yield (25%), whereas the branch regioselectivity was exclusive (entry 8).\textsuperscript{20} The ring-saturated C\textsubscript{2}-symmetric carbene ligand \[\text{(S,S)-L7}\], which has two stereogenic carbon centers in the imidazolidine ring and two mesityl groups at both nitrogen atoms, induced virtually no reaction (entry 9).\textsuperscript{21} The N-hydroxyalkyl-substituted carbene ligand (L\textsubscript{8}) having a stereogenic center in the N-alkyl side arm promoted no reaction (entry 10).\textsuperscript{22} Thus, having the alkanol in place of the arenol was not suitable.

Results with achiral catalyst systems are also listed in Table 1 (entries 11–16). The reaction did not occur at all without a ligand or with 1,10-phenanthroline, Ph\textsubscript{3}P or DPPE ligands (entries 11–14). However, a copper-carbene complex prepared \textit{in situ} from 1,3-bis(2,4,6-trimethylphenyl)imidazolium chloride (IMes·HCl), CuCl and LiOrBu gave 4aa in low yield (25%) with exclusive \(\gamma\)-regioselectivity (entry 15). The use of 1,3-bis(2,4,6-trimethylphenyl)imidazolinium tetrafluoroborate (SIMes·HBF\textsubscript{4}) resulted in virtually no reaction (entry 16).

Results of the reaction conducted with other hydrosilane reagents (L\textsubscript{1}-Cu, 0 °C) are shown in Table 1, entries 17–21. Siloxane-type hydrosilane (Me\textsubscript{2}HSi)\textsubscript{2}O (1b) was as effective as Me\textsubscript{2}PhSiH (1a) (entry 17), but poly(methylhydrosiloxane) (1c) gave a low product yield (42%) albeit a high level of enantioselectivity (entry 18). Relatively small trialkylsilane EtMe\textsubscript{2}SiH (1d) was as effective as Me\textsubscript{2}PhSiH (1a), but sterically more demanding trialkylsilanes such as Et\textsubscript{3}SiH (1e) or \(t\text{Bu}Me\textsubscript{2}SiH (1f)\) did not participate in the reaction (entries 19–21).

The nature of the Lewis base additives had a significant impact on the reaction efficiency and enantioselectivity (Table 1, entries 22–25). When the cation of LiOrBu was changed to K\textsuperscript{+} (KOrBu) or Na\textsuperscript{+} (NaOrBu) under the optimized conditions, the product yields were low and the enantioselectivity decreased slightly (entries 22 and 23). The additive with a smaller alkoxide, LiOMe, induced virtually no reaction (entry 24). Li\textsubscript{2}CO\textsubscript{3} caused no reaction (entry 25).
Substrates

Other isocyanides also participated in the enantioselective reaction with PhMe₂SiH (1a) and allylic phosphate 3a under identical conditions (Table 2). The reaction of benzyl isocyanide (2b) occurred with excellent enantioselectivity, affording, after hydrolysis, aldehyde (S)-5a with 99% ee in 89% yield (entry 1). The reaction of t-butyl isocyanide (2c) also occurred with high enantioselectivity (93% ee), but the yield of (S)-5a was only moderate (50%) due to slower copper catalysis accompanied by decomposition of the allylic phosphate (entry 2). The reaction of 4-methoxyphenyl isocyanide (2d) gave the corresponding N-arylformimide [(S)-4da] with 99% ee in 94% yield (entry 3).

*Reaction conditions: 1a (0.18 mmol), 2 (0.165 mmol), 3 (0.15 mmol), CuCl/L1 (10 mol %), LiO−Bu (0.195 mmol), THF (0.6 mL), 0 °C, 24 h. X, OP(O)(OEt)2 or Cl. Bn, benzyl. PMP, p-methoxyphenyl. THP, 2-tetrahydropyranyl. TBS, tert-butyldimethylsilyl. Yield of isolated product. Constitutional isomer ratio branched/linear >99:1 (determined by 1H NMR analysis of the crude product). The enantiomeric excess was determined by HPLC analysis.*
Entries 3, 9, 17: 4 was hydrolyzed with 2 M HCl aq. Entries 1, 2, 16, 18–20: 4 was hydrolyzed with silica gel. 5 mol % of CuCl/L1 was used. Reaction for 48 h. 2.5 mol % of CuCl/L1 was used. Reaction for 72 h. Poly(methylhydrosiloxane) (1c) was used.

The potential for scaling up the copper-catalyzed reaction was examined on a preparative scale. Thus, the reaction of 1a (1.19 g, 8.44 mmol), 2d (1.06 g, 7.74 mmol), and 3a (2.0 g, 7.04 mmol) yielded 1.51 g (81%) of (S)-4da with 99% ee (Table 2, entry 5). The Cu loading could be reduced to 5 or 2.5 mol% with the enantioselectivity retained (entries 6 and 7).

Table 2 also summarizes the results of the reactions of various (Z)-γ,γ-disubstituted allylic phosphates having aryl and alkyl substituents at the γ-position under the CuCl-L1 catalyst system. 4-methoxyphenyl isocyanide (2d) was used as an isocyanide reagent because N-(4-methoxyphenyl)formimide products are generally more hydrolytically stable than N-alkylformimidites. The former could be isolated by chromatography on silica gel. The N-(4-methoxyphenyl)formimidites were readily converted to the corresponding aldehydes upon acidic hydrolysis (2 M HCl aq). The methyl group of 3a could be replaced with an ethyl group with virtually no deviation in enantioselectivity (entry 8). Remarkably, the allylic phosphate [(Z)-3c], with a sterically more demanding cyclohexyl group at the γ-position, also participated in the reaction to produce a significantly sterically congested quaternary stereogenic center with excellent enantioselectivity (entry 9). Various functional groups such as methoxy, THP ether, fluoro, ethoxy carbonyl and chloro substituents were tolerated at the meta- or para-positions of the aromatic γ-substituent of the allylic phosphate (entries 10–15). The p-tolyl- and 2-naphthyl-substituted allylic substrates were also suitable (entries 16 and 17).

Furthermore, the copper catalyst system was applicable for the reaction of allylic substrates having two alkyl substituents at the γ-position albeit with somewhat decreased enantioselectivities. Thus, the reactions of allylic phosphate 3k having methyl and phenylethyl groups at the γ-position with 2a or 2d occurred under the optimal reaction conditions with exclusive branch selectivities, affording the corresponding products [(R)-5k and (R)-4dk] with 83% ee in aldehyde or imine forms, respectively (entries 19 and 20). The combination of chloride as a leaving group and poly(methylhydrosiloxane) as a hydrosilane caused an increase in enantioselectivity (86% ee) (entry 22). Alkene [(Z)-3l′] and silyl ether [(Z)-3m′] moieties in the aliphatic γ-substituent of the allylic chloride were compatible with the reaction (entries 23 and 24). The reaction of γ-monosubstituted allylic substrates did not give the corresponding formimide products with tertiary stereogenic centers, but gave trisubstituted alkenes and conjugate dienes, which were produced through isomerization of the three-component coupling products and elimination reaction of the allylic substrates, respectively.
In all entries in Table 2, the copper catalysis afforded neither simple hydride reduction products\textsuperscript{23} nor isocyanide 1,1-hydrosilylation products.\textsuperscript{2} In addition, the two-component reaction between hydrosilane 1\textsubscript{a} and allylic phosphate (Z)-3\textsubscript{a} (1.1/1) in the presence of a stoichiometric amount of LiOrBu (1.3 eq) and a catalytic amount of the CuCl-L\textsubscript{1} system (10 mol%) in THF at 0 °C over 24 h gave only a trace amount of simple reduction product 3-phenylbutene (3% yield). In the absence of the allylic phosphate (3\textsubscript{a}), the two-component reaction between 1\textsubscript{a} and isocyanide 2\textsubscript{d} (1.2/1) under otherwise identical conditions did not afford the isocyanide 1,1-hydrosilylation product with complete recovery of the two substrates. These results imply that a copper(I) hydride (Cu–H) species might not be a reactive intermediate in the three-component coupling reaction catalyzed by the Cu-naphthol-carbene system, but a mechanism involving such a species is not ruled out by these results.

The reaction of (E)-3\textsubscript{a} or (E)-3\textsubscript{k} with E-configuration under the optimized conditions provided the antipode of the product derived from the corresponding (Z)-isomer in excellent product yield and with excellent branch selectivity (> 99:1) (Table 2, entries 25 and 26). This result suggests that Z alkenes are more favorable substrates than E alkenes and that the substitution pattern at the β carbon is more important than that at the γ carbon for enantioselection by the catalyst.

**Considerations for reaction pathways**

This copper-catalyzed three-component coupling presumably goes through the formation of a lithium aryloxo(formimidoyl)cuprate species (E) followed by its formal S\textsubscript{N}2’ reaction with allylic substrate 3 (Figure 2a and 2b). For the formation of the formimidoylcopper(I) species (E), two types of reaction pathways are conceivable. One involves isocyanide 1,1-insertion into a Cu–H bond (copper hydride pathway, Figure 2a), and the other is direct reaction of hydrosilane, isocyanide-Cu(I) complex (A) and LiOrBu (hydrosilicate pathway, Figure 2b).
Figure 2. Possible reaction pathways for the formation of formimidoylcopper(I) species. a) Copper hydride pathway. b) Hydrosilicate pathway. Ar, 2,4-Cy2-6-Me-C₆H₄.

In the copper hydride pathway (Figure 2a), the reaction of CuCl, L₁, LiOᵗBu, and isocyanide 2 forms (L₁–H)-Cu(I)-isocyanide complex A, in which the chiral carbene ligand coordinates to Cu as an anionic C,O-bidentate ligand (L₁–H). Transmetalation between A and a hydrosilane (1) produces a η¹-formimidoylcopper species (B). Next, isocyanide insertion into the Cu–H bond may form a η¹-formimidoylcopper species (C), which undergoes transmetalation between its aryloxysilane moiety and LiOᵗBu to form a lithium aryloxo(formimidoyl)cuprate (E). Alternatively, formation of aryloxo(formimidoyl)cuprate E may proceed through prior activation of the silyl ether moiety of B by LiOᵗBu to form a cuprate species (D) followed by isocyanide 1,1-insertion to the Cu–H bond.

On the other hand, the hydrosilicate pathway (Figure 2b) does not form a Cu–H bond. Thus, the aryloxocuppper(I) isocyanide complex A recruits LiOᵗBu Lewis base through an O···Li⁺···O ionic bridge to activate the hydrosilane reagent (1), forming a hydrosilicate species F. The nucleophilic hydrosilicate moiety attacks the positively charged isocyanide terminal carbon that is in close proximity, producing lithium aryloxo(formimidoyl)cuprate E.

Although we do not rule out either reaction pathway at present, the hydrosilicate pathway (Figure 2b) better explains the critical roles of the ligand hydroxyl group (Table 1, entry 1 with L₁ vs. entry 7 with L⁷) for the promotion of the reaction because the naphthoxo group directly
participate in the formation of the formimidoyl-copper structure only in the hydrosilicate pathway. In addition, preliminary NMR or FTIR studies on stoichiometric reactions with CuCl, L1, LiOrBu, hydrosilane 1a, and benzyl isocyanide (2b) (1/1/3/1/1) in THF-\(d_8\) (for NMR) or THF (for FTIR) at room temperature indicated coordination of the isocyanide (2b) to Cu in an asymmetric environment, interaction of LiOrBu with the Cu-isocyanide complex, and the formation of a formimidoyl-copper species upon addition of the hydrosilane (1a) (See below). During these NMR or FTIR experiments, no evidence of the formation of Cu–H species was obtained. These spectroscopic results are also in support of the hydrosilicate pathway.

When the arenol group was absent in the carbene ligand, the tBuO ion derived from the added Lewis base may have taken place the role of the ligand naphthoxo group, forming a lithium t-butoxo(formimidoyl)cuprate (Table 1, entries 8 and 15). The lower reaction efficiencies with these systems can be deduced to unfavorable steric and entropy effects in the intermolecular participation of the bulky alkoxide anion for the formation of the (alkoxo)formimidoylcuprate. The increased steric demand of the cuprate would also be unfavorable for the subsequent formal S\(_{N2'}\) reaction with the allylic substrate.
NMR Studies for the Stoichiometric Reaction

CuCl (3.0 mg, 0.03 mmol), L1·HBF₄ (21.2 mg, 0.03 mmol), LiOtBu (5.0 mg, 0.06 mmol) and THF-d₈ (0.75 mL) were placed in an NMR tube. The tube was sealed, evacuated, and filled with argon. After shaking the mixture for 15 min at 25 °C and measuring a ¹H NMR spectrum (Figure 3), benzyl isocyanide (2b) (3.7 μL, 0.03 mmol) was added (See also Figure 8 for ¹H NMR spectrum for 2b), and the mixture was shaken for 15 min at 25 °C: a ¹H NMR signal for the benzyl protons of the isocyanide (2b) appeared as an AB quartet (δ 4.59 and 4.67 ppms, J = 17.2 Hz), indicating coordination of the isocyanide (2b) to Cu in an asymmetric environment (Figure 4).

Next, LiOtBu (2.5 mg, 0.03 mmol) was added, and the resulting mixture was shaken for 15 min at 25 °C: the signal for the benzyl protons shifted from δ 4.59 and 4.67 ppms (J = 17.2 Hz) to δ 4.48 and 4.60 ppms (J = 17.2 Hz), suggesting interaction of LiOtBu with the Cu-isocyanide complex (Figure 5). Subsequently, PhMe₂SiH (4.8 μL, 0.03 mmol) was added to the mixture (See also Figure 9 for ¹H NMR spectrum for PhMe₂SiH), and the mixture was shaken for 1.5 h at 25 °C, the ¹H NMR spectrum showed a new characteristic peak at δ 9.98 ppm, consistent with the formation of a formimidoylcopper species [Cu-C(=NBn)-H] (Figure 6). The signal for the benzyl protons shifted from δ 4.48 and 4.60 ppms (J = 17.2 Hz) to δ 4.61 and 4.71 ppms (J = 17.2 Hz). The prolonged reaction time (48 h) resulted in further increase of this signal and decrease of the signals for the PhMe₂SiH (Figure 7). This spectrum change was accompanied by gradual downfield shift of the benzyl protons and disappearance of the ²J_H-H coupling (s, δ 4.87 ppm), suggesting dynamic nature of the reaction mixture and dissociation of imidoyl moieties from chirally modified metal complex fragments. Finally, one equiv of the allylic phosphate was added to the mixture. However, the formation of three-component coupling product 4ba was not detected.
Figure 3. $^1$H NMR spectrum for the reaction of CuCl, L1·HBF$_4$ and LiOrBu (1/1/2) (400 MHz, THF-$d_8$)

FTIR Studies for the Stoichiometric Reaction

CuCl (1.5 mg, 0.015 mmol), L1-HBF₄ (10.6 mg, 0.015 mmol), LiOttBu (2.5 mg, 0.03 mmol) and THF (1.0 mL) were placed in a vial containing a magnetic stirring bar. The vial was sealed with a Teflon®-coated silicon rubber septum, and then the vial was evacuated and filled with argon. After stirring for 15 min at 25 °C (Figure 10), benzyl isocyanide (2b) (1.8 μL, 0.015 mmol) was added (See also Figure 14 for FTIR spectrum for 2b). The mixture was stirred for 15 min at 25 °C, and transferred to a NaCl cell (0.1 mm path length cell) under argon atmosphere: the FTIR spectrum showed an intense absorption of the isocyanide NC stretching at 2171 cm⁻¹. This wave number is larger than that of free 2b (2149 cm⁻¹), indicating Cu coordination of 2b (Figure 11). Next, LiOttBu (1.2 mg, 0.015 mmol) was added (See also Figure 15 for FTIR spectrum for LiOttBu), and the resulting mixture was stirred for 15 min at 25 °C: the absorption band in the isocyanide did not change (Figure 12). Subsequently, PhMe₂SiH (2.4 μL, 0.015 mmol) was added to the mixture (See also Figure 16 for FTIR spectrum for PhMe₂SiH), and the mixture was stirred for 48 h at 25 °C: the FTIR spectrum showed an absorption at 1680 cm⁻¹, consistent with the formation of imidoyl species (Figure 13).

Considerations for Enantioselection Mechanism

When the lithium aryloxo(formimidoyl)cuprate intermediate (E) assumed above reacts with the prochiral allylic substrate (3) in a formal S<sub>n</sub>2’ manner, either the Cu atom or the imidoyl C(sp<sup>2</sup>) atoms may attack the γ carbon of 3. Furthermore, the possibility for the intervention of bond formation between the aryloxo O atom of L1 and the α or γ carbon atoms of 3 should not be ruled out. This complicated situation hampers the development of a model to explain the highly efficient enantioselection by the Cu-L1 catalyst at present. However, it is likely that the Li<sup>+</sup> ion, bridging the isocyanide N and aryloxo O atoms in E, plays an essential role in the enantioselection. Thus, a Li<sup>+</sup> ion located at a well-defined position in a chiral environment would fix the rotation of the formimidoyl ligand around the Cu–C(imidoyl, sp<sup>2</sup>) axis and assist the reaction of E with 3 in a cooperative manner through binding to the leaving group, limiting possible enantioselectivity-determining transition state conformers. Based on these considerations, the decreased efficiency of NaOEtBu and KOEtBu may reflect lower Lewis acidities of Na and K cations or lower solubility of species involving these cations (Table 1, entries 2, 22, and 23).

Product Derivatization

The enantioenriched α-quaternary formimide (S)-4da and aldehyde (S)-5a obtained by the
Enantioselective copper catalysis were used to demonstrate the synthetic utility of this methodology (Figure 15). Formimide (S)-4da was readily converted to primary alcohol (S)-6a through acidic hydrolysis followed by NaBH₄ reduction (Figure 15a). Reduction of (S)-4da with NaBH₄ followed by removal of the PMP group through treatment with cerium ammonium nitrate afforded secondary amine (S)-7a (Figure 15a). The NaBH₄ reduction of (S)-4da and N-allylation followed by ring-closing alkene metathesis produced the N-heterocyclic six-membered ring compound (S)-8a (Figure 15a). The α-quaternary aldehyde could be transformed to 2,2-disubstituted 3-butenenitrile [(S)-9j] or 2,5-dienoate [(S)-10a] via Horner-Wadsworth-Emmons reaction (Figures 15b and c).

**Figure 15.** Derivatizations of α-quaternary formimide and aldehyde. a) Synthesis of primary alcohol, primary amine and N-heterocyclic six-membered ring compound. CAN, ceric ammonium nitrate. b) Synthesis of allylic nitrile. Ac, acetyl. CDI, carbonyldiimidazole. c) Horner-Wadsworth-Emmons reaction.
Conclusion

A copper-catalyzed asymmetric three-component coupling reaction of isocyanides, hydrosilanes, and γ,γ-disubstituted primary allylic phosphates or chlorides occurred with exclusive regioselectivity and with high enantioselectivities to yield chiral α-quaternary formimides, which were readily converted to the corresponding aldehydes. This enantioselective copper catalysis was enabled by a combined use of original chiral naphthol-carbene ligand of Sawamura and Ohmiya group as a functional supporting ligand for Cu and LiOtBu as a stoichiometric Lewis basic activator for Si. Owing to the mildness of the reaction conditions, various functional groups were tolerated in the substrates. The formimidoyl group and vinyl group in the three-component coupling products can be used as handles for further transformations. This copper catalysis presumably goes through a lithium aryloxo(formimidoyl)cuprate intermediate, which was previously undescribed in the literature. Possible participation of the ionized ligand naphtholic hydroxy group in the formation of the formimidoylcuprate species is proposed (hydrosilicate pathway). Mechanistic studies by intermediate analysis and theoretical calculations are underway. The enantioselective copper catalysis presented here provides a new strategy for asymmetric synthesis using isocyanides as reagents for umpolung C1 synthons.

Experimental Section
Instrumentation and Chemicals

NMR spectra were recorded on a JEOL ECX-400, operating at 400 MHz for 1H NMR and 100.5 MHz for 13C NMR. Chemical shift values for 1H and 13C are referenced to Me4Si and the residual solvent resonances, respectively. Chemical shifts are reported in δ ppm. Mass spectra were obtained with Thermo Fisher Scientific Exactive, JEOL JMS-T100LP or JEOL JMS-700TZ at the Instrumental Analysis Division, Global Facility Center, Creative Research Institution, Hokkaido University. HPLC analyses were conducted on a HITACHI ELITE LaChrom system with a HITACHI L-2455 diode array detector or a HITACHI Chromaster with a HITACHI 5430 diode array detector. Optical rotations were measured on a JASCO P-2200. TLC analyses were performed on commercial glass plates bearing 0.25-mm layer of Merck Silica gel 60F254 or commercial glass plates bearing 0.25-mm layer of diol-modified silica gel (Fuji Silysia Chemical Ltd., Chromatorex). Silica gel (Kanto Chemical Co., Silica gel 60 N, spherical, neutral), diol-modified silica gel (Fuji Silysia Chemical Ltd., Chromatorex, Diol MB100-40/75) or aluminum oxide (Nacalai Tesuque, Alumina Activated 200) were used for column chromatography. IR spectra were measured with a Perkin-Elmer Spectrum One. Gel permeation chromatography (GPC) was performed by LaboACE LC-5060 (Japan Analytical Industry Ltd., two in-line JAIGEL-HR, ethyl acetate, 10 mL/min, UV and RI detectors).
All reactions were carried out under nitrogen or argon atmosphere. Materials were obtained from commercial suppliers or prepared according to standard procedures unless otherwise noted. CuCl, and LiOrBu were purchased from Aldrich Chemical Co., stored under nitrogen, and used as received. THF was purchased from Kanto Chemical Co., and purified by passage through activated alumina under positive argon pressure as described by Grubbs et al. Isocyanides \( \text{2a, b} \) were purchased from TCI Chemical Co., stored under nitrogen, and used as received. \( \text{2c} \) was purchased from Aldrich Chemical Co., stored under nitrogen, and used as received. PhMe\(_2\)SiH, (Me\(_2\)HSi)\(_2\)O, Et\(_3\)SiH and \( \text{tBuMe}_2\)SiH were purchased from TCI Chemical Co., stored under nitrogen, and used as received. poly(methylhydrosiloxane) was purchased from Sant Cruz Biotechnology Inc., stored under nitrogen, and used as received. Carbene Ligands \( \text{L6–8} \) are found in the literature.\(^{25-27}\)

**Preparation of Allylic Substrates**

**Preparation of (Z)-3a, (Z)-3b, (Z)-3d–f and (Z)-3i, (Z)-3j.** Allylic phosphates were prepared through carbocupration of alkynoate, DIBAL-H reduction followed by phosphorylation. The preparation of (Z)-3a is representative (Scheme 1). To a solution of CuI (3.14 g, 16.5 mmol) in THF (44.0 mL) was added methyllithium (1.1 M in Et\(_2\)O, 30.0 mL, 33.0 mmol) at –40 °C, and the resulting mixture was stirred at –40 °C for 30 min. To the mixture was added ethyl 3-phenylpropiolate (2.61 g, 15.0 mmol) dropwise at –78 °C, and the mixture was stirred at –78 °C for 2 h. Saturated NH\(_4\)Cl aq was added and the mixture was allowed to warm to room temperature. The resulting slurry was diluted with EtOAc (60.0 mL) and washed with NH\(_4\)Cl aq and brine. The organic layer was separated and dried over MgSO\(_4\). Then, the drying agent was removed by filtration, and the resulting solution was evaporated under reduced pressure. The residue was purified by flash chromatography on silica gel (0–1% EtOAc/hexane) provided alkenoate (2.28 g, 12.0 mmol) in 80% yield.

To a stirred solution of alkenoate (1.90 g, 10.0 mmol) in CH\(_2\)Cl\(_2\) was dropped DIBAL-H (21.6 mL in 1.02 M hexane solution, 22.0 mmol) at –78 °C and the reaction was stirred for 2 h at the same temperature. Sat. NH\(_4\)Cl was added and the mixture was vigorously stirred at room temperature for 10 min. Solid was filtered through a pad of celite and the filtrate was evaporated under reduced pressure. The crude product was purified by flash chromatography on silica gel (5–20% EtOAc/hexane) to give allylic alcohol (1.41 g, 9.5 mmol) in 95% yield.

To a solution of (Z)-3-phenyl-2-buten-1-ol (296.4 mg, 2.0 mmol) and DMAP (61.1 mg, 0.5 mmol) in pyridine (2.7 mL), (EtO\(_2\))_3P(O)Cl (406 μL, 2.7 mmol) was added at 0 °C. After being stirred at room temperature for 12 h, the reaction mixture was diluted with EtOAc (20.0 mL) and was treated with water (5.0 mL). The resulting mixture was washed with saturated CuSO\(_4\) aq.
(10.0 mL × 3) and was dried over anhydrous MgSO₄, filtered, and evaporated under reduced pressure. The residue was purified by GPC to provide (Z)-3a (483 mg, 1.7 mmol) in 85% yield.

Scheme 1. Preparation of (Z)-3a, (Z)-3b, (Z)-3d–f and (Z)-3i, (Z)-3j

**Preparation of (Z)-3g.** Allylic phosphate was prepared through the phosphorylation of the corresponding allylic alcohol obtained by the reported palladium catalyzed reaction of 2-butyn-1-ol and ethyl 4-iodobenzoate (Scheme 2).₂⁸ To a solution of the allylic alcohol (220 mg, 1.0 mmol) and DMAP (30.6 mg, 0.25 mmol) in pyridine (1.4 mL), (EtO)₂P(O)Cl (194 μL, 1.35 mmol) was added at 0 °C. After being stirred at room temperature for 12 h, the reaction mixture was diluted with EtOAc (5 mL) and was treated with water (2.5 mL). The resulting mixture was washed with saturated CuSO₄ aq. (5.0 mL × 3) and brine, and was dried over anhydrous MgSO₄, filtered, and evaporated under reduced pressure. The residue was purified by GPC to provide (Z)-3g (285 mg, 0.8 mmol) in 80% yield.

Scheme 2. Preparation of (Z)-3g

**Preparation of (Z)-3h.** Allylic phosphate was prepared through Negishi cross-coupling, DIBAL–H reduction followed by phosphorylation (Scheme 3). To a stirred solution of 1-bromo-4-chlorobenzene (957 mg, 5.0 mmol) in THF (4.7 mL) was dropped nBuLi (3.1 mL in 1.65 M hexane solution, 5.0 mmol) at −78 °C and the reaction was continued for 10 min at the same temperature. Next, ZnCl₂ (682 mg, 5.0 mmol) in THF (2.0 mL) was added to the mixture at −78
100 °C. The reaction mixture was allowed to warm to room temperature, stirred for another 45 min to prepare arylzinc reagent. To a suspension of Pd(PPh₃)₄ (46.2 mg, 40.0 µmol) and alkenyltosylate (1.1 g, 4.0 mmol) in THF (4.0 mL) was added the arylzinc reagent at room temperature. After being stirred at room temperature for 1.5 h, the reaction mixture was quenched with saturated NH₄Cl aq. The aqueous layer was extracted with EtOAc, and the combined organic layer was washed with brine. The mixture was dried over anhydrous MgSO₄, filtered, and evaporated under reduced pressure. The residue was purified by flash column chromatography on silica gel (0–3% EtOAc/hexane) to give alkenoate (719 mg, 3.2 mmol) in 80% yield.

To a stirred solution of alkenoate (382 mg, 1.7 mmol) in CH₂Cl₂ was dropped DIBAL-H (3.6 mL in 1.02 M hexane solution, 3.7 mmol) at −78 °C and the reaction was stirred for 2 h at the same temperature. Sat. NH₄Cl was added and the mixture was vigorously stirred at room temperature for 10 min. Solid was filtered through celite pad and the filtrate was evaporated under reduced pressure. The crude product was purified by flash chromatography on silica gel (5–20% EtOAc/hexane) to give allylic alcohol (292 mg, 1.6 mmol) in 95% yield.

To a solution of the allylic alcohol (182 mg, 1.0 mmol) and DMAP (30.6 mg, 0.3 mmol) in pyridine (1.4 mL), (EtO)₂P(O)Cl (194 µL, 1.4 mmol) was added at 0 °C. After being stirred at room temperature for 12 h, the reaction mixture was diluted with EtOAc (5.0 mL) and was treated with water (2.5 mL). The resulting mixture was washed with saturated CuSO₄ aq. (5.0 mL × 3) and brine, and was dried over anhydrous MgSO₄, filtered, and evaporated under reduced pressure. The residue was purified by GPC to provide (Z)-3h in 85% yield (271 mg, 0.85 mmol).

Scheme 3. Preparation of (Z)-2h

Preparation of (Z)-3c and (E)-3a. Allylic phosphates were prepared through Horner-Wadsworth-Emmons reaction of acetophenone, DIBAL-H reduction followed by phosphorylation. The preparation of (E)-3a is representative (Scheme 4). To a solution of NaH (982 mg, 22.5 mmol)
in THF (40.0 mL) was added triethyl phosphonoacetate (4.76 mL, 24.0 mmol) dropwise at 0 °C, and the resulting mixture was stirred at 0 °C for 30 min. To the mixture was added acetophenone (1.80 g, 15.0 mmol) at room temperature and the mixture was stirred at the same temperature for 12 h. Saturated NH₄Cl aq was added. The resulting slurry was diluted with EtOAc (50.0 mL) and washed with water and brine. The organic layer was separated and dried over MgSO₄. Then, the drying agent was removed by filtration, and the resulting solution was evaporated. The residue was purified by flash chromatography on silica gel (0–1% EtOAc/hexane) provided alkenoate (20.0 g, 10.5 mmol) in 70% yield.

To a stirred solution of alkenoate (20.0 g, 10.5 mmol) in CH₂Cl₂ was dropped DIBAL-H (22.7 mL in 1.02 M hexane solution, 23.2 mmol) at −78 °C and the reaction was continued for 2 h at the same temperature. Sat. NH₄Cl was added and the mixture was vigorously stirred for 10 min. Solid was filtered through celite pad and the filtrate was evaporated under reduced pressure. The crude product was purified by flash chromatography on silica gel (10–50% EtOAc/hexane) to give allylic alcohol (1.48 g, 10.0 mmol) in 95% yield.

To a solution of allylic alcohol (296 mg, 2.0 mmol) and Et₃N (307 μL, 2.2 mmol) in CH₂Cl₂ (10 mL), (EtO)₂P(O)Cl (301 μL, 2.0 mmol) and DMAP (48.9 mg, 0.4 mmol) were sequentially added at 0 °C. The reaction mixture was allowed to warm to room temperature, stirred for another 12 h, diluted with EtOAc (20 mL) and was treated with water (5 mL). The aqueous layer was extracted with EtOAc, and the combined organic layer was washed with water and brine. The organic layer was separated and dried over MgSO₄. Then, the drying agent was removed by filtration, and the resulting solution was evaporated under reduced pressure. The residue was purified by GPC to provide (E)-3a (455 mg, 1.6 mmol) in 80% yield.

Scheme 4. Preparation of (Z)-2c and (E)-3a

Characterization Data for Allylic Substrates

(Z)-3a and (E)-3a are found in the literature.
(Z)-Diethyl(3-phenyl-2-penten-1-yl)phosphate (3b)

Colorless Oil. IR (neat) 702, 824, 963, 996, 1095, 1263, 1443, 1655, 2934, 2979 cm$^{-1}$. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 1.00 (t, $J = 7.2$ Hz, 3H), 1.30 (t, $J = 7.2$ Hz, 6H), 2.41 (q, $J = 7.2$ Hz, 2H), 4.07 (quintet, $J = 7.2$ Hz, 4H), 4.44 (t, $J = 7.2$ Hz, 2H), 5.67 (t, $J = 7.2$ Hz, 1H), 7.12–7.14 (m, 2H), 7.27–7.36 (m, 3H). $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 12.5, 16.1 (d, $J = 6.7$ Hz), 31.7, 63.6 (d, $J = 5.7$ Hz), 65.0 (d, $J = 5.7$ Hz), 7.05–7.08 (m, 2H), 7.25–7.34 (m, 3H). HRMS–ESI (m/z): [M+Na]$^+$ calcd for C$_{15}$H$_{23}$O$_4$NaP, 321.12262; found, 321.12234.

(Z)-3-Cyclohexyl-3-phenylallyl Diethyl Phosphate (3c)

Colorless Oil. IR (neat) 703, 820, 978, 1009, 1166, 1263, 1443, 1653, 2927, 2983 cm$^{-1}$. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 1.07–1.30 (m, 11H), 1.66 (m, 1H), 1.73–1.78 (m, 4H), 2.20 (t, $J = 11.2$ Hz, 1H), 4.05 (quintet, $J = 7.2$ Hz, 4H), 4.36 (t, $J = 7.2$ Hz, 2H), 5.61 (t, $J = 7.2$ Hz, 1H), 7.05–7.08 (m, 2H), 7.25–7.34 (m, 3H). $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 16.1 (d, $J = 7.7$ Hz), 26.2, 26.5, 31.9, 45.7, 63.5 (d, $J = 5.7$ Hz), 65.2, 119.3 (d, $J = 6.7$ Hz), 127.1, 128.0, 128.3, 139.7, 152.4. HRMS–ESI (m/z): [M+Na]$^+$ calcd for C$_{19}$H$_{29}$O$_4$NaP, 375.16957; found, 375.16936.

(Z)-Diethyl[3-(3-methoxyphenyl)-2-buten-1-yl]phosphate (3d)

Colorless Oil. IR (neat) 704, 789, 978, 1025, 1167, 1252, 1429, 1487, 1577, 2982 cm$^{-1}$. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 1.30 (t, $J = 7.2$ Hz, 6H), 2.10 (d, $J = 1.2$ Hz, 3H), 3.81 (s, 3H), 4.08 (quintet, $J = 7.2$ Hz, 4H), 4.47 (t, $J = 7.2$ Hz, 2H), 5.70 (td, $J = 7.2, 1.2$ Hz, 1H), 6.72–6.77 (m, 2H), 6.83 (dd, $J = 8.0, 2.4$ Hz, 1H), 7.26 (t, $J = 8.0$ Hz, 1H). $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 16.1 (d, $J = 6.7$ Hz), 25.3, 55.1, 63.6 (d, $J = 5.7$ Hz), 64.9 (d, $J = 4.8$ Hz), 112.7, 113.4, 120.0, 121.7 (d, $J = 7.7$ Hz), 129.3, 141.5, 142.7, 159.4. HRMS–ESI (m/z): [M+Na]$^+$ calcd for C$_{15}$H$_{23}$O$_3$NaP, 337.11753; found, 337.11717.
(Z)-Diethyl(3-{3-[(tetrahydro-2H-pyran-2-yl)oxy]phenyl}-2-buten-1-yl)phosphate (3e)

Colorless Oil. **IR** (neat) 732, 820, 1026, 1166, 1261, 1394, 1490, 1656, 2910, 2982 cm⁻¹. **¹H NMR** (400 MHz, CDCl₃) δ 1.30 (t, J = 7.2 Hz, 6H), 1.59–1.74 (m, 3H), 1.84–1.88 (m, 2H), 1.96–2.09 (m, 4H), 3.62 (m, 1H), 3.91 (m, 1H), 4.08 (quintet, J = 7.2 Hz, 4H), 4.49 (t, J = 7.2 Hz, 2H), 5.42 (t, J = 3.2 Hz, 1H), 5.68 (t, J = 7.2 Hz, 1H), 6.79 (d, J = 8.0 Hz, 1H), 6.86 (m, 1H), 7.00 (m, 1H), 7.25 (t, J = 8.0 Hz, 1H). **¹³C NMR** (100 MHz, CDCl₃) δ 16.0 (d, J = 6.7 Hz), 18.8, 25.1, 25.2, 30.3, 62.1, 63.6 (d, J = 5.7 Hz), 64.9 (d, J = 4.8 Hz), 96.3, 115.2, 115.9, 120.9, 121.7 (d, J = 7.7 Hz), 129.2, 141.3, 142.5, 156.9. **HRMS–ESI** (m/z): [M+Na]⁺ calcd for C₁₉H₂₉O₆NaP, 407.15940; found, 407.15939.

(Z)-Diethyl[3-(4-fluorophenyl)-2-buten-1-yl]phosphate (3f)

Colorless Oil. **IR** (neat) 726, 818, 979, 1025, 1162, 1223, 1261, 1508, 1603, 2983 cm⁻¹. **¹H NMR** (400 MHz, CDCl₃) δ 1.31 (t, J = 7.2 Hz, 6H), 2.09 (d, J = 1.2 Hz, 3H), 4.09 (quintet, J = 7.2 Hz, 4H), 4.44 (t, J = 7.2 Hz, 2H), 5.72 (td, J = 7.2, 1.2 Hz, 1H), 7.04 (dd, J = 8.8, 8.8 Hz, 2H), 7.16 (dd, J = 8.8, 5.2 Hz, 2H). **¹³C NMR** (100 MHz, CDCl₃) δ 16.1 (d, J = 6.7 Hz), 25.4, 63.6 (d, J = 5.7 Hz), 64.8 (d, J = 4.8 Hz), 115.2 (d, J = 20.9 Hz), 121.9 (d, J = 6.7 Hz), 129.3 (d, J = 8.5 Hz), 135.9 (d, J = 2.9 Hz), 141.9, 162.1 (d, J = 245.0 Hz). **HRMS–ESI** (m/z): [M+Na]⁺ calcd for C₁₄H₂₀O₄FNaP, 325.09755; found, 325.09775.

(Z)-Ethyl 4-{4-[(Diethoxyphosphoryl)oxy]-2-buten-2-yl}benzoate (3g)

Pale Yellow Oil. **IR** (neat) 710, 864, 995, 1025, 1103, 1271, 1394, 1609, 1716, 2983 cm⁻¹. **¹H NMR** (400 MHz, CDCl₃) δ 1.31 (t, J = 7.2 Hz, 6H), 1.40 (t, J = 7.2 Hz, 3H), 2.12 (s, 3H), 4.08 (quintet, J = 7.2 Hz, 4H), 4.36–4.45 (m, 4H), 5.78 (t, J = 7.2 Hz, 1H), 7.26 (d, J = 8.0 Hz, 2H), 8.03 (d, J = 8.0 Hz, 2H). **¹³C NMR** (100 MHz, CDCl₃) δ 14.3, 16.1 (d, J = 6.7 Hz), 25.0, 61.0, 63.6 (d, J = 4.7 Hz), 64.6 (d, J = 4.7 Hz), 122.7 (d, J = 6.7 Hz), 127.7, 129.5, 141.9 (× 2C), 144.7, 166.2. **HRMS–ESI** (m/z): [M+Na]⁺ calcd for C₁₄H₂₅O₆NaP, 379.12810; found, 379.12784.
(Z)-3-(4-Chlorophenyl)-2-buten-1-yl Diethyl Phosphate (3h)

Colorless Oil. IR (neat) 704, 818, 1000, 1028, 1182, 1261, 1434, 1576, 2944 cm$^{-1}$. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 1.31 (t, $J = 7.2$ Hz, 6H), 2.09 (s, 3H), 4.09 (quintet, $J = 7.2$ Hz, 4H), 4.43 (t, $J = 7.2$ Hz, 2H), 5.73 (t, $J = 7.2$ Hz, 1H), 7.12 (d, $J = 8.0$ Hz, 2H), 7.32 (d, $J = 8.0$ Hz, 2H). $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 16.1 (d, $J = 6.7$ Hz), 25.2, 63.6 (d, $J = 5.7$ Hz), 64.7 (d, $J = 4.8$ Hz), 122.2 (d, $J = 7.6$ Hz), 128.4, 129.0, 133.3, 138.4, 141.7. HRMS–ESI (m/z): [M+Na]$^+$ calcd for C$_{14}$H$_{20}$O$_4$ClNaP, 341.06799; found, 341.06781.

(Z)-Diethyl [3-(p-tolyl)-2-buten-1-yl]phosphate (3i)

Colorless Oil. IR (neat) 747, 816, 978, 1026, 1166, 1261, 1445, 1512, 1654, 2982 cm$^{-1}$. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 1.30 (t, $J = 7.2$ Hz, 6H), 2.09 (s, 3H), 2.35 (s, 3H), 4.08 (quintet, $J = 7.2$ Hz, 4H), 4.48 (t, $J = 7.2$ Hz, 2H), 5.69 (t, $J = 7.2$ Hz, 1H), 7.07 (d, $J = 8.0$ Hz, 2H), 7.15 (d, $J = 8.0$ Hz, 2H). $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 16.1 (d, $J = 6.7$ Hz), 21.1, 25.3, 63.6 (d, $J = 5.7$ Hz), 65.1 (d, $J = 5.7$ Hz), 121.3 (d, $J = 7.6$ Hz), 127.6, 128.9, 137.0, 137.2, 142.8. HRMS–ESI (m/z): [M+Na]$^+$ calcd for C$_{15}$H$_{23}$O$_4$NaP, 321.12262; found, 321.12251.

(Z)-Diethyl[3-(naphthalen-2-yl)-2-buten-1-yl]phosphate (3j)

Colorless Oil. IR (neat) 748, 819, 978, 1025, 1260, 1393, 1443, 1504, 1599, 2981 cm$^{-1}$. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 1.27 (t, $J = 7.2$ Hz, 6H), 2.19 (s, 3H), 4.07 (quintet, $J = 7.2$ Hz, 4H), 4.52 (t, $J = 7.2$ Hz, 2H), 5.81 (t, $J = 7.2$ Hz, 1H), 7.32 (d, $J = 8.0$ Hz, 1H), 7.45–7.51 (m, 2H), 7.62 (s, 1H), 7.81–7.84 (m, 3H). $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 16.0 (d, $J = 6.7$ Hz), 25.3, 63.6 (d, $J = 5.7$ Hz), 65.0 (d, $J = 5.7$ Hz), 122.0 (d, $J = 7.6$ Hz), 125.7, 126.0, 126.2, 126.5, 127.6, 127.9, 127.9, 132.6, 133.0, 137.5, 142.8. HRMS–ESI (m/z): [M+Na]$^+$ calcd for C$_{18}$H$_{25}$O$_4$NaP, 357.12262; found, 357.12240.

Procedure for Asymmetric Three-Component Coupling

The reaction in Table 1, entry 2 is representative. CuCl (1.5 mg, 0.015 mmol), L1•HBF$_4$...
(10.6 mg, 0.015 mmol) and LiOtBu (16.1 mg, 0.195 mmol) were placed in a vial containing a magnetic stirring bar. The vial was sealed with a Teflon®-coated silicon rubber septum, and then the vial was evacuated and filled with argon. THF (0.6 mL) was added to the vial, and then the mixture was stirred at room temperature for 10 min. Next, PhMe₂SiH (27.9 µL, 0.18 mmol) and cyclohexyl isocyanide (2a) (18.0 mg, 20.0 mmol) were added. Finally, allylic phosphate 3a (42.6 mg, 0.15 mmol) was added at 0 °C. After 24 h stirring at 0 °C, the reaction mixture was diluted with hexane (2.0 mL). The reaction mixture was filtered through a short plug of aluminum oxide (1.0 g) with diethyl ether as an eluent. The resulting solution was evaporated under reduced pressure, and the residue was filtered through a short plug of silica gel (3.0 g) [(S)-4aa was hydrolyzed]. After volatiles were removed under reduced pressure, flash column chromatography on silica gel (0–1% EtOAc/hexane) gave (S)-5a (21.1 mg, 0.132 mmol) in 88% yield.

The reaction in Table 2, entry 3 is representative. CuCl (1.5 mg, 0.015 mmol), L₁•HBF₄ (10.6 mg, 0.015 mmol) and LiOtBu (16.1 mg, 0.195 mmol) were placed in a vial containing a magnetic stirring bar. The vial was sealed with a Teflon®-coated silicon rubber septum, and then the vial was evacuated and filled with argon. THF (0.6 mL) was added to the vial, and then the mixture was stirred at room temperature for 10 min. Next, PhMe₂SiH (27.9 µL, 0.18 mmol) and 4-methoxyphenyl isocyanide (2c) (22.6 mg, 0.165 mmol) were added. Finally, allylic phosphate 3a (42.6 mg, 0.15 mmol) was added at 0 °C. After 24 h stirring at 0 °C, the reaction mixture was diluted with hexane (2.0 mL). The reaction mixture was filtered through a short plug of aluminum oxide (1.0 g) with diethyl ether as an eluent. The filtrate was evaporated under reduced pressure, flash column chromatography on diol-modified silica gel (hexane) gave (S)-4ca (37.4 mg, 0.141 mmol) in 94% yield.

To a solution of the formimide (S)-4ca in diethyl ether (0.56 mL) was added 2M HCl aq. (0.21 mL) at 0°C. After stirring at room temperature for 2 h, the reaction mixture was diluted with diethyl ether and extracted with diethyl ether (2.0 mL × 3). The combined organic layer was washed with saturated NaHCO₃ aq., water and brine, and was dried over anhydrous MgSO₄, filtered, and evaporated under reduced pressure to give (S)-5a as a colorless oil (22.6 mg, 0.141 mmol, quant.).

A gram scale reaction (Table 2, entry 5). The reaction in Table 2, entry 5 is representative. CuCl (69.7 mg, 0.70 mmol), L₁•HBF₄ (498 mg, 0.70 mmol) and LiOtBu (755 mg, 9.15 mmol) were placed in a vial containing a magnetic stirring bar. The vial was sealed with a Teflon®-coated silicon rubber septum, and then the vial was evacuated and filled with argon. THF (28.2 mL) was added to the vial, and then the mixture was stirred at room temperature for 10 min. Next, PhMe₂SiH (1.19 g, 8.44 mmol) and 4-methoxyphenyl isocyanide (2c) (1.06 g, 7.74 mmol) were added. Finally, allylic phosphate 3a (2.0 g, 7.04 mmol) was added at 0 °C. After 24 h stirring at 0
106 °C, the reaction mixture was diluted with hexane (60.0 mL). The reaction mixture was filtered through a short plug of aluminum oxide (10.0 g) with diethyl ether as an eluent. After volatiles were removed under reduced pressure, flash column chromatography on diol-modified silica gel (0–1% EtOAc/hexane) gave (S)-4da (1.51 g, 5.69 mmol) in 81% yield.

**Characterization Data for α-Quaternary Formimides and Aldehydes (S)-2-Methyl-2-phenyl-3-butenal (5a)**

![Structure of 5a](image)

The product 5a was purified by flash chromatography on silica gel (0–1% EtOAc/hexane) (Table 1, entry 2; 21.1 mg, 0.132 mmol, 88% isolated yield from (Z)-3a, Table 2, entry 1; 21.4 mg, 0.134 mmol, 89% isolated yield from (Z)-3a, Table 2, entry 2; 12.0 mg, 0.075 mmol, 50% isolated yield from (Z)-3a, Table 2, entry 3; 22.6 mg, 0.141 mmol, 94% isolated yield from (Z)-3a). Colorless Oil. **IR** (neat) 761, 922, 1029, 1078, 1387, 1446, 1492, 1724, 2713, 2814, 2982 cm⁻¹. **¹H NMR** (400 MHz, CDCl₃) δ 1.54 (s, 3H), 5.19 (d, J = 17.6 Hz, 1H), 5.42 (d, J = 10.0 Hz, 1H), 6.22 (dd, J = 17.6, 10.0 Hz, 1H), 7.25 (d, J = 7.2 Hz, 2H), 7.30 (t, J = 7.2 Hz, 1H), 7.39 (t, J = 7.2 Hz, 2H), 9.58 (s, 1H). **¹³C NMR** (100 MHz, CDCl₃) δ 20.1, 57.8, 117.4, 127.4 (× 2C), 128.9, 138.2, 140.0, 199.4. **HRMS–APCI** (m/z): [M+H]+ calcd for C₁₁H₁₃O, 161.09609; found, 161.09618. [α]D₂⁴ –43.16 (c 0.93, CHCl₃). The absolute configuration of 5a was determined to be S by the optical rotation of 5a obtained by reduction with NaBH₄ from 5a. (S)-2-Methyl-2-phenyl-3-buten-1-ol (6a): [α]D²⁶ +29.29 (99% ee, c 0.72, ethanol). {lit³⁰, (R) isomer, 81% ee, [α]D²⁶ –18.1 (1.9, ethanol)}.

Table 1, entry 2; the ee value (97% ee) was determined by chiral HPLC analysis of 6a obtained by reduction with NaBH₄ from 5a [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 97:3, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 15.1 min for R isomer and 16.0 min for S isomer].

Table 2, entry 1; the ee value (99% ee) was determined by chiral HPLC analysis of 6a obtained by reduction with NaBH₄ from 5a [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 97:3, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 15.1 min for R isomer and 16.0 min for S isomer].
The product 4da was purified by flash chromatography on diol-modified silica gel (hexane) (Table 2, entry 3; 37.4 mg, 0.141 mmol, 94% isolated yield from (Z)-3a, Table 2, entry 5; 801 mg, 3.02 mmol, 86% isolated yield from (Z)-3a). Pale Yellow Oil. IR (neat) 761, 827, 1243, 1293, 1444, 1504, 1647, 2835, 2979 cm$^{-1}$. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 1.68 (s, 3H), 3.80 (s, 3H), 5.14 (d, $J = 17.6$ Hz, 1H), 5.31 (d, $J = 10.8$ Hz, 1H), 6.33 (dd, $J = 17.6$, 10.8 Hz, 1H), 6.87 (d, $J = 8.8$ Hz, 2H), 7.06 (d, $J = 8.8$ Hz, 2H), 7.25 (m, 1H), 7.33–7.38 (m, 4H), 7.90 (s, 1H). $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 23.0, 51.2, 55.5, 114.2, 114.8, 121.9, 126.8, 127.2, 142.0, 143.8, 145.1, 157.8, 166.8. HRMS–ESI (m/z): [M+H]$^+$ calcd for C$_{18}$H$_{20}$ON, 266.15394; found, 266.15397. $^[$#ref]{$^a$}$D_{27}^{25}$ $-25.97$ (99% ee, $c 0.95$, CHCl$_3$). The absolute configuration of 4da was determined to be S by the optical rotation of the corresponding aldehyde 5a. The geometry of formimidoyl moiety was determined by NOESY experiment.

Table 2, entry 3; the ee value (99% ee) was determined by chiral HPLC analysis of 4da [CHIRALCEL$^\text{®}$ AD-3 column, 4.6 mm $\times$ 250 mm, Daicel Chemical Industries, hexane/2-propanol = 97:3, 0.5 mL/min, 40 ºC, 220 nm UV detector, retention time = 11.3 min for $R$ isomer and 11.8 min for $S$ isomer].

Table 2, entry 5; the ee value (99% ee) was determined by chiral HPLC analysis of 4da [CHIRALCEL$^\text{®}$ AD-3 column, 4.6 mm $\times$ 250 mm, Daicel Chemical Industries, hexane/2-propanol = 97:3, 0.5 mL/min, 40 ºC, 220 nm UV detector, retention time = 10.6 min for $R$ isomer and 11.3 min for $S$ isomer].

The product 4db was purified by flash chromatography on diol-modified silica gel (hexane) (37.7 mg, 0.135 mmol, 90% isolated yield from (Z)-3b). Pale Yellow Oil. IR (neat) 757, 828, 919, 1034, 1242, 1293, 1505, 1580, 1645, 2878, 2935, 2969 cm$^{-1}$. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 0.90 (t, $J = 7.2$ Hz, 3H), 2.15–2.29 (m, 2H), 3.79 (s, 3H), 5.05 (dd, $J = 18.0$, 1.2 Hz, 1H), 5.35 (dd, $J = 10.8$, 1.2 Hz, 1H), 6.37 (dd, $J = 18.0$, 10.8 Hz, 1H), 6.87 (d, $J = 9.2$ Hz, 2H), 7.05 (d, $J = 9.2$ Hz, 2H), 7.25 (m, 1H), 7.31–7.38 (m, 4H), 7.87 (s, 1H). $^{13}$C NMR (100 MHz, CDCl$_3$)
δ 9.1, 29.3, 54.7, 55.4, 114.1, 116.1, 121.8, 126.7, 128.0, 128.4, 140.8, 142.2, 145.3, 157.8, 166.7.

7. **HRMS–ESI (m/z):** [M+H]+ calcd for C_{19}H_{22}ON, 280.16959; found, 280.16946. [a]_D^{23} +15.58 (c 1.30, CHCl_3). The ee value (96% ee) was determined by chiral HPLC analysis of 4db [CHIRALCEL® AD-3 column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 97:3, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 11.9 min for R isomer and 12.7 min for S isomer]. The absolute configuration of 4db was assigned by consideration of the stereochemical pathway.

(R,E)-2-Cyclohexyl-N-(4-methoxyphenyl)-2-phenyl-3-buten-1-imine (4dc)

![Diagram of (R,E)-2-Cyclohexyl-N-(4-methoxyphenyl)-2-phenyl-3-buten-1-imine (4dc)]

The product 4dc was purified by flash chromatography on diol-modified silica gel (hexane) (44.7 mg, 0.134 mmol, 89% isolated yield from (Z)-3c). Pale Yellow Oil. **IR** (neat) 751, 828, 910, 1034, 1242, 1446, 1504, 1543, 2853, 2927 cm⁻¹. **¹H NMR** (400 MHz, CDCl_3) δ 0.84–1.12 (m, 3H), 1.22–1.40 (m, 2H), 1.64–1.76 (m, 4H), 1.93 (d, J = 11.2 Hz, 1H), 2.44 (tt, J = 12.0, 2.8 Hz, 1H), 3.79 (s, 3H), 5.02 (dd, J = 18.0, 1.2 Hz, 1H), 5.40 (dd, J = 10.8, 1.2 Hz, 1H), 6.39 (dd, J = 18.0, 10.8 Hz, 1H), 6.86 (d, J = 8.8 Hz, 2H), 7.02 (d, J = 8.8 Hz, 2H), 7.24 (m, 1H), 7.30–7.36 (m, 4H), 7.87 (s, 1H). **¹³C NMR** (100 MHz, CDCl_3) δ 26.7, 26.9 (× 2C), 28.4, 29.0, 43.5, 55.5, 58.0, 114.1, 116.8, 121.7, 126.5, 128.1, 128.8, 139.8, 141.2, 145.6, 157.7, 166.5. **HRMS–ESI (m/z):** [M+H]+ calcd for C_{23}H_{28}ON, 334.21654; found, 334.21631. [a]_D^{23} +24.07 (c 1.09, CHCl_3). The ee value (97% ee) was determined by chiral HPLC analysis of 4dc [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/OD-3 column, 4.6 mm × 220 mm/OD-H column, 4.6 mm × 220 mm, Daicel Chemical Industries, hexane/2-propanol = 99:1, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 26.0 min for S isomer and 26.7 min for R isomer]. The absolute configuration of 4dc was assigned by consideration of the stereochemical pathway.

(S,E)-2-(3-Methoxyphenyl)-N-(4-methoxyphenyl)-2-methyl-3-buten-1-imine (4dd)

![Diagram of (S,E)-2-(3-Methoxyphenyl)-N-(4-methoxyphenyl)-2-methyl-3-buten-1-imine (4dd)]

The product 4dd was purified by flash chromatography on diol-modified silica gel (hexane) (41.3 mg, 0.140 mmol, 93% isolated yield from (Z)-3d). Pale Yellow Oil. **IR** (neat) 773, 830, 1035, 1242, 1290, 1504, 1580, 1599, 1647, 2835, 2935 cm⁻¹. **¹H NMR** (400 MHz, CDCl_3) δ 1.67
(s, 3H), 3.80 (s, 6H), 5.15 (dd, J = 17.2, 1.2 Hz, 1H), 5.31 (dd, J = 10.8, 1.2 Hz, 1H), 6.32 (dd, J = 17.2, 10.8 Hz, 1H), 6.80 (d, J = 8.4 Hz, 1H), 6.87 (d, J = 8.8 Hz, 2H), 6.90 (t, J = 2.0 Hz, 1H), 6.93 (m, 1H), 7.05 (d, J = 8.8 Hz, 2H), 7.28 (t, J = 8.4 Hz, 1H), 7.88 (s, 1H). $^{13}$C NMR (100 MHz, CDCl$_3$) δ 22.9, 51.1, 55.2, 55.4, 111.6, 113.5, 114.1, 114.9, 119.6, 121.9, 129.5, 141.8, 145.1, 145.5, 157.8, 159.7, 166.6. HRMS–ESI (m/z): [M+H]$^+$ calcd for C$_{19}$H$_{22}$O$_2$N, 296.16451; found, 296.16448. $[\alpha]_D^{25} = -17.32$ (c 1.13, CHCl$_3$). The ee value (98% ee) was determined by chiral HPLC analysis of 4dd [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 99.5:0.5, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 13.5 min for R isomer and 15.3 min for S isomer]. The absolute configuration of 4dd was assigned by consideration of the stereochemical pathway.

(S)-2-(3-Methoxyphenyl)-2-methyl-3-butenal (5d)

![Chemical structure of 5d](image)

Colorless Oil. IR (neat) 779, 924, 1045, 1257, 1485, 1582, 1599, 1725, 2713, 2836, 2981 cm$^{-1}$. $^1$H NMR (400 MHz, CDCl$_3$) δ 1.53 (s, 3H), 3.81 (s, 3H), 5.19 (d, J = 18.0 Hz, 1H), 5.41 (d, J = 10.8 Hz, 1H), 6.21 (dd, J = 18.0, 10.8 Hz, 1H), 6.79–6.86 (m, 3H), 7.31 (t, J = 8.0 Hz, 1H), 9.57 (s, 1H). $^{13}$C NMR (100 MHz, CDCl$_3$) δ 20.0, 55.2, 57.8, 112.4, 113.6, 117.5, 119.7, 129.9, 138.1, 141.6, 160.0, 199.2. HRMS–ESI (m/z): [M+Na]$^+$ calcd for C$_{11}$H$_{14}$O$_2$Na, 213.08860; found, 213.08905. $[\alpha]_D^{25} = -43.45$ (c 0.90, CHCl$_3$). The absolute configuration of 5d was assigned by consideration of the stereochemical pathway.

(S,E)-N-(4-Methoxyphenyl)-2-methyl-2-{3-[(tetrahydro-2H-pyran-2-yloxy]phenyl}-3-buten-1-imine (4de) (Diastereomeric ratio 1:1)

![Chemical structure of 4de](image)

The product 4de was purified by flash chromatography on diol-modified silica gel (0–1% EtOAc/hexane) (49.3 mg, 0.135 mmol, 90% isolated yield from (Z)-3e). Pale Yellow Oil. IR (neat) 773, 872, 968, 1036, 1109, 1243, 1505, 1579, 1647, 2873, 2944 cm$^{-1}$. $^1$H NMR (400 MHz, CDCl$_3$) δ 1.58–1.71 (m, 0.5 × 6H, 0.5 × 6H), 1.83–1.87 (m, 0.5 × 2H, 0.5 × 2H), 1.96–2.06 (m, 0.5 × 1H, 0.5 × 1H), 3.56–3.62 (m, 0.5 × 1H, 0.5 × 1H), 3.80 (0.5 × 3H, 0.5 × 3H), 3.88–3.94 (m,
0.5 × 1H, 0.5 × 1H); 5.12–5.18 (dd, J = 17.2, 1.2 Hz, 0.5 × 1H, 0.5 × 1H); 5.29–5.32 (dd, J = 11.2, 1.2 Hz, 0.5 × 1H, 0.5 × 1H), 5.39–5.41 (t, J = 3.2 Hz, 0.5 × 1H, 0.5 × 1H), 6.28–6.36 (dd, J = 17.2, 11.2 Hz, 0.5 × 1H, 0.5 × 1H), 6.86–6.88 (d, J = 8.8 Hz, 0.5 × 2H, 0.5 × 2H), 6.95–6.99 (m, 0.5 × 2H, 0.5 × 2H), 7.02–7.03 (t, J = 2.0 Hz, 0.5 × 1H, 0.5 × 1H), 7.04–7.07 (d, J = 8.8 Hz, 0.5 × 2H, 0.5 × 2H), 7.25–7.28 (t, J = 8.0 Hz, 0.5 × 1H, 0.5 × 1H), 7.88 (s, 0.5 × 1H, 0.5 × 1H). 1H NMR (100 MHz, CDCl3) δ 18.9, 18.9, 22.9, 22.9, 25.2, 25.2, 30.4, 30.4, 51.1, 51.1, 55.5, 55.5, 62.1, 62.1, 96.4, 96.4, 114.1, 114.1, 114.3, 114.3, 114.8, 114.8, 115.9, 116.0, 120.5, 120.5, 121.9, 121.9, 129.4, 129.4, 141.8, 141.9, 145.1, 145.1, 145.3, 145.4, 157.3, 157.3, 157.8, 157.8, 166.7, 166.7. HRMS–ESI (m/z): [M+H]+ calcd for C23H28O3N, 366.20637; found, 366.20648. [α]b25 +14.58 (c 0.99, CHCl3). The ee value (99% ee) was determined by chiral HPLC analysis of 4de [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/OD-3 column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 99.5:0.5, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 46.2 min and 67.2 min for S isomer and 49.1 min and 64.9 min for R isomer]. The absolute configuration of 4de was assigned by consideration of the stereochemical pathway.

(S,E)-2-(4-Fluorophenyl)-N-(4-methoxyphenyl)-2-methyl-3-buten-1-imine (4df)

The product 4df was purified by flash chromatography on diol-modified silica gel (hexane) (3.83 mg, 0.135 mmol, 90% isolated yield from (Z)-3f). Pale Yellow Oil. IR (neat) 774, 828, 1034, 1162, 1243, 1394, 1504, 1602, 1646, 2836, 2979 cm⁻¹. 1H NMR (400 MHz, CDCl3) δ 1.66 (s, 3H), 3.80 (s, 3H), 5.13 (dd, J = 17.6, 1.2 Hz, 1H), 5.31 (dd, J = 10.4, 1.2 Hz, 1H), 6.30 (dd, J = 17.6, 10.4 Hz, 1H), 6.87 (d, J = 9.2 Hz, 2H), 7.01–7.07 (m, 4H), 7.30 (dd, J = 9.2, 5.2 Hz, 2H), 7.86 (s, 1H). 13C NMR (100 MHz, CDCl3) δ 23.3, 50.7, 55.5, 114.2, 115.0, 115.3 (d, J = 21.9 Hz), 121.9, 128.9 (d, J = 7.6 Hz), 139.4 (d, J = 2.8 Hz), 141.9, 144.9, 157.9, 161.7 (d, J = 244.0 Hz), 166.3. HRMS–ESI (m/z): [M+H]+ calcd for C18H15ONF, 284.14452; found, 284.14435. [α]b27 –30.81 (c 1.20, CHCl3). The ee value (96% ee) was determined by chiral HPLC analysis of 4df [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 99:1, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 21.1 min for R isomer and 22.0 min for S isomer]. The absolute configuration of 4df was assigned by consideration of the stereochemical pathway.
Ethyl (S,E)-4-{1-[(4-Methoxyphenyl)imino]-2-methyl-3-buten-2-yl}benzoate (4dg)

The product 4dg was purified by flash chromatography on diol-modified silica gel (0–2% EtOAc/hexane) (46.6 mg, 0.138 mmol, 92% isolated yield from (Z)-3g). Pale Yellow Oil. IR (neat) 770, 1019, 1102, 1243, 1272, 1505, 1647, 2835, 2980 cm⁻¹. ¹H NMR (400 MHz, CDCl₃) δ 1.39 (t, J = 6.8 Hz, 3H), 1.69 (s, 3H), 3.80 (s, 3H), 4.37 (q, J = 6.8 Hz, 2H), 5.15 (d, J = 17.2 Hz, 1H), 5.34 (d, J = 10.8, 1H), 6.32 (dd, J = 17.2, 10.8 Hz, 1H), 6.88 (d, J = 8.8 Hz, 2H), 7.06 (d, J = 8.8 Hz, 2H), 7.42 (d, J = 8.8 Hz, 2H), 7.89 (s, 1H), 8.03 (d, J = 8.8 Hz, 2H). ¹³C NMR (100 MHz, CDCl₃) δ 14.3, 23.1, 51.4, 55.5, 60.9, 114.2, 115.4, 121.9, 127.3, 129.0, 129.8, 141.4, 144.8, 148.9, 158.0, 165.8, 166.4. HRMS-ESI (m/z): [M+H]+ calcd for C₂₁H₂₃O₂N, 338.17507; found, 338.17523. [α]b₂⁴ –6.34 (c 1.15, CHCl₃). The ee value (97% ee) was determined by chiral HPLC analysis of 4dg [CHIRALCEL® AD-3 column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 95:5, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 20.0 min for R isomer and 21.6 min for S isomer]. The absolute configuration of 4dg was assigned by consideration of the stereochemical pathway.

(S,E)-2-(4-Chlorophenyl)-N-(4-methoxyphenyl)-2-methyl-3-buten-1-imine (4dh)

The product 4dh was purified by flash chromatography on diol-modified silica gel (hexane) (39.6 mg, 0.132 mmol, 88% isolated yield from (Z)-3h). Pale Yellow Oil. IR (neat) 777, 824, 922, 1012, 1095, 1293, 1243, 1505, 1647, 2835, 2980 cm⁻¹. ¹H NMR (400 MHz, CDCl₃) δ 1.66 (s, 3H), 3.80 (s, 3H), 5.13 (d, J = 17.6 Hz, 1H), 5.32 (d, J = 10.8 Hz, 1H), 6.29 (dd, J = 17.6, 10.8 Hz, 1H), 6.87 (d, J = 8.8 Hz, 2H), 7.50 (d, J = 8.8 Hz, 2H), 7.26–7.34 (m, 4H), 7.86 (s, 1H). ¹³C NMR (100 MHz, CDCl₃) δ 23.1, 50.8, 55.5, 114.2, 115.2, 121.9, 128.6, 128.7, 132.7, 141.6, 142.2, 144.8, 158.0, 166.0. H RMS-ESI (m/z): [M+H]+ calcd for C₁₉H₁₇ClNO, 300.11497; found, 300.11509. [α]b₂⁴ –15.62 (c 1.21, CHCl₃). The ee value (95% ee) was determined by chiral HPLC analysis of 4dh [CHIRALCEL® AD-3 column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-
propanol = 97:3, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 11.1 min for R isomer and 12.1 min for S isomer]. The absolute configuration of 4dh was assigned by consideration of the stereochemical pathway.

\( (S,E)-N-(4-Methoxyphenyl)-2-methyl-2-(\rho\text{-tolyl})-3\text{-buten-1-imine} (4di) \)

The product 4di was purified by flash chromatography on diol-modified silica gel (hexane) (39.8 mg, 0.143 mmol, 95% isolated yield from (Z)-3i). Pale Yellow Oil. IR (neat) 721, 816, 828, 919, 1035, 1243, 1504, 1580, 1646, 2835, 2978 cm\(^{-1}\). \( ^1\text{H NMR} \) (400 MHz, CDCl\(_3\)) \( \delta \) 1.66 (s, 3H), 2.34 (s, 3H), 3.80 (s, 3H), 5.13 (dd, \( J = 17.6, 1.2 \text{ Hz}, 1 \text{H} \)), 5.29 (dd, \( J = 10.4, 1.2 \text{ Hz}, 1 \text{H} \)), 6.32 (dd, \( J = 17.6, 10.4 \text{ Hz}, 1 \text{H} \)), 6.86 (d, \( J = 9.2 \text{ Hz}, 2 \text{H} \)), 7.05 (d, \( J = 9.2 \text{ Hz}, 2 \text{H} \)), 7.17 (d, \( J = 8.4 \text{ Hz}, 2 \text{H} \)), 7.23 (d, \( J = 8.4 \text{ Hz}, 2 \text{H} \)), 7.87 (s, 1H). \( ^{13}\text{C NMR} \) (100 MHz, CDCl\(_3\)) \( \delta \) 20.9, 23.0, 50.8, 55.4, 114.1, 114.6, 121.9, 127.1, 129.3, 136.4, 140.7, 142.2, 145.1, 157.8, 166.9. (R,E)-N-(4-Methoxyphenyl)-2-methyl-2-phenethyl-3-buten-1-imine (4dk)

![Chemical Structure](s2m2m.png)

The product 4dk was purified by flash chromatography on diol-modified silica gel (hexane) (39.6 mg, 0.135 mmol, 90% isolated yield from (Z)-3k). Pale Yellow Oil. IR (neat) 731, 828, 1035, 1210, 1242, 1455, 1505, 1604, 1648, 2835, 2932 cm⁻¹. ¹H NMR (400 MHz, CDCl₃) δ 1.36 (s, 3H), 1.93–2.00 (m, 2H), 2.57–2.69 (m, 2H), 3.80 (s, 3H), 5.14 (dd, J = 18.0, 1.2 Hz, 1H), 5.22 (dd, J = 10.8, 1.2 Hz, 1H), 6.02 (dd, J = 18.0, 10.8 Hz, 1H), 6.86 (d, J = 8.8 Hz, 2H), 7.00 (d, J = 8.8 Hz, 2H), 7.16–7.20 (m, 3H), 7.24–7.29 (m, 2H), 7.71 (s, 1H). ¹³C NMR (100 MHz, CDCl₃) δ 21.0, 30.8, 40.5, 46.1, 55.4, 114.1, 114.2, 121.7, 125.8, 128.3, 128.4, 142.5, 142.6, 145.3, 157.7, 168.4. HRMS–ESI (m/z): [M+H]+ calcd for C₂₀H₂₁ON, 294.18524; found, 294.18546. [α]D²⁴ –19.09 (c 1.11, CHCl₃). The ee value (84% ee) was determined by chiral HPLC analysis of 4dk [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/OD-3 column, 4.6 mm × 220 mm, Daicel Chemical Industries, hexane/2-propanol = 98:2, 0.7 mL/min, 40 °C, 220 nm UV detector, retention time = 26.7 min for S isomer and 29.5 min for R isomer]. The absolute configuration of
$4dk$ was determined to be $R$ by the optical rotation of the corresponding formaldehyde $5k$. The geometry of formimidoyl moiety was determined by NOESY experiment.

**(R)-2-Methyl-2-phenethyl-3-butenal (5k)**

![Structure](image)

The product $5k$ was purified by flash chromatography on silica gel (0–2% EtOAc/hexane) (Table 2, entry 19; 25.3 mg, 0.134 mmol, 89% isolated yield from (Z)-3k, Table 2, entry 20; 25.4 mg, 0.135 mmol, 90% isolated yield from (Z)-3k, Table 2, entry 22; 16.9 mg, 0.09 mmol, 60% isolated yield from (Z)-3k'). $5k$ was consistent with the literature data.\(^{31}\) $[\alpha]_D^{23}$ −19.89 (86% ee, c 0.90, CH$_2$Cl$_2$) \{lit\(^{31}\), (S) isomer, >99% ee, $[\alpha]_D^{25}$ +26.7 (c 1.15, CH$_2$Cl$_2$)\}.

Table 2, entry 19; the ee value (83% ee) was by chiral HPLC analysis was obtained by reduction with NaBH$_4$ from $5k$ [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/OD-3 column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 95:5, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 38.6 min for $S$ isomer and 40.4 min for $R$ isomer].

Table 2, entry 22; the ee values (86% ee) was determined by chiral HPLC analysis was obtained by reduction with NaBH$_4$ from $5k$ [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/OD-3 column, 4.6 mm × 250 mm, Daicel Chemical Industries, hexane/2-propanol = 95:5, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 39.1 min for $S$ isomer and 40.9 min for $R$ isomer].

**(R)-2,6-Dimethyl-2-vinyl-5-heptenal (5l)**

![Structure](image)

The product $5l$ was purified by flash chromatography on silica gel (0–2% EtOAc/hexane) (15.0 mg, 0.09 mmol, 60% isolated yield from (Z)-3l'). $5l$ was consistent with the literature data.\(^{32}\) $[\alpha]_D^{22} −8.76$ (c 1.21, CHCl$_3$). The ee value (88% ee) was determined by chiral HPLC analysis of $N$-(4-methoxyphenyl)formimide derivative obtained by the reaction between $5l$ and 4-methoxyphenylamine [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/OD-3 column, 4.6 mm × 220 mm, Daicel Chemical Industries, hexane/2-propanol = 99.5:0.5, 0.7 mL/min, 40 °C, 220 nm UV detector, retention time =13.6 min for $R$ isomer and 14.3 min for $S$ isomer]. The absolute configuration of $5l$ was assigned by consideration of the stereochemical pathway.
(R)-2-{2-[(tert-Butyldimethylsilyloxy)ethyl]-2-methyl-3-butenal (5m)

The product 5m was purified by flash chromatography on silica gel (0–2% EtOAc/hexane) (16.7 mg, 0.069 mmol, 46% isolated yield from (Z)-3m'). Pale Yellow Oil. **IR** (neat) 775, 834, 921, 1095, 1255, 1388, 1464, 1727, 2858, 2930, 2956 cm⁻¹. **¹H NMR** (400 MHz, CDCl₃)  δ 0.02 (s, 3H), 0.03 (s, 3H), 0.87 (s, 9H), 1.19 (s, 3H), 1.79 (ddd, J = 14.0, 5.6, 5.6 Hz, 1H), 2.00 (ddd, J = 14.0, 7.2, 6.4 Hz, 1H), 3.61–3.71 (m, 2H), 5.13 (d, J = 18.0 Hz, 1H), 5.25 (d, J = 10.0 Hz, 1H), 5.83 (dd, J = 18.0, 10.0 Hz, 1H), 9.40 (s, 1H). **¹³C NMR** (100 MHz, CDCl₃) δ –5.6, 18.1, 18.2, 25.8, 39.1, 51.2, 59.0, 116.2, 138.8, 202.0. **HRMS** –ESI (m/z): [M+Na]⁺ calcd for C₁₀H₂₀O₂NaSi, 265.15943; found, 265.15980. **[α]D₂₆** +18.34 (c 1.11, CHCl₃). The ee value (84% ee) was determined by chiral HPLC analysis of N-(4-methoxyphenyl)formimide derivative obtained by the reaction between 5m and 4-methoxyphenylamine [CHIRALCEL® OD-3 column, 4.6 mm x 250 mm/OD-3 column, 4.6 mm x 220 mm, Daicel Chemical Industries, hexane/2-propanol = 99.5:0.5, 0.7 mL/min, 40 °C, 220 nm UV detector, retention time =12.4 min for R isomer and 13.3 min for S isomer]. The absolute configuration of 5m was assigned by consideration of the stereochemical pathway.

(R,E)-N-(4-Methoxyphenyl)-2-methyl-2-phenyl-3-buten-1-imine (4da)

The product 4da was purified by flash chromatography on diol-modified silica gel (hexane) (34.2 mg, 0.129 mmol, 86% isolated yield from (E)-3a). **[α]D₂₃** +15.45 (c 0.99, CHCl₃). The ee value (66% ee) was determined by chiral HPLC analysis of 4da. [CHIRALCEL® AD-3 column, 4.6 mm x 250 mm, Daicel Chemical Industries, hexane/2-propanol = 97:3, 0.5 mL/min, 40 °C, 220 nm UV detector, retention time = 10.1 min for R isomer and 11.0 min for S isomer].

(S,E)-N-(4-Methoxyphenyl)-2-methyl-2-phenethyl-3-buten-1-imine (4dk)

The product 4dk was purified by flash chromatography on diol-modified silica gel (hexane) (40.5 mg, 0.138 mmol, 92% isolated yield from (E)-3k). **[α]D₂₄** +15.63 (c 1.32, CHCl₃). The ee
value (70% ee) was determined by chiral HPLC analysis of 4dk [CHIRALCEL® OD-3 column, 4.6 mm × 250 mm/OD-3 column, 4.6 mm × 220 mm, Daicel Chemical Industries, hexane/2-propanol = 98:2, 0.7 mL/min, 40 °C, 220 nm UV detector, retention time = 26.8 min for S isomer and 29.8 min for R isomer].

**Procedures for Product Derivatization (Figure 15)**

**Synthesis of primary alcohol (Figure 15a).**

To a solution of (S)-4da (37.4 mg, 0.141 mmol) in diethyl ether (0.56 mL) was added 2 M HCl aq. (0.21 mL) at 0°C. After stirring at rt for 2 h, the reaction mixture was diluted with diethyl ether and extracted with diethyl ether (2.0 mL × 3). The combined organic layer was washed with saturated NaHCO₃ aq., water and brine, and was dried over anhydrous MgSO₄, filtered, and evaporated under reduced pressure to give (S)-5a as a colorless oil (22.6 mg, 0.141 mmol, quant.).

To a solution of (S)-5a in MeOH (1.0 mL) was added NaBH₄ (11.3 mg, 0.3 mmol) at 0 °C. The reaction mixture was allowed to warm to room temperature, stirred for another 30 min, water was added. The aqueous layer was extracted with EtOAc, and the combined organic layer was washed with water and brine. The mixture was dried and concentrated *in vacuo*. Purification by column chromatography (silica gel, 5–30% EtOAc/hexane) yielded (S)-6a (15.7 mg, 0.097 mmol) in 97% yield. Pale Yellow Oil. 5a was consistent with the literature data.³⁰ [α]D₂₆ +29.29 (c 0.72, ethanol).

**Synthesis of primary amine (Figure 15a)**

To a solution of (S)-4da (133 mg, 0.5 mmol) in EtOH (5.0 mL) was added NaBH₄ (189 mg, 5.0 mmol). The reaction mixture was stirred at 60 °C for 12 h, quenched with water. The aqueous layer was extracted with EtOAc, and the combined organic layer was washed with water and brine, and was dried over anhydrous Na₂SO₄, filtered, and evaporated under reduced pressure to give secondary amine as a pale yellow oil (131 mg, 0.49 mmol) in 98% yield. To a solution of the secondary amine (53.5 mg, 0.2 mmol) in CH₃CN (2.0 mL) was added ceric ammonium nitrate (548 mg, 1.0 mmol) in water (2.0 mL) at room temperature. After being stirred at room temperature for 2 h, the reaction mixture was diluted with Et₂O (4.0 mL) and water (4.0 mL). The aqueous layer was extracted with Et₂O, and the combined organic layer was washed with water and brine, and was dried over anhydrous Na₂SO₄, filtered, and evaporated under reduced pressure to give (S)-7a as a red oil (27.1 mg, 0.168 mmol) in 84% yield. Pale Yellow Oil. IR (neat) 761, 812, 915, 1029, 1374, 1413, 1445, 1494, 1645, 2968 cm⁻¹. ¹H NMR (400 MHz, CDCl₃) δ 1.39 (s, 3H), 2.95 (dd, J = 13.2 Hz, 1H), 3.00 (dd, J = 13.2 Hz, 1H), 5.10 (dd, J = 17.2, 1.2 Hz, 1H), 5.23 (dd, J = 10.8, 1.2 Hz, 1H), 6.07 (dd, J = 17.6, 10.8 Hz, 1H), 7.22 (m, 1H), 7.33–7.37 (m, 4H). ¹³C NMR (100 MHz, CDCl₃) δ 23.1, 46.7, 51.6, 113.7, 126.2, 126.8, 128.4, 144.6,
145.5. HRMS–ESI (m/z): [M+H]+ calcld for C_{11}H_{16}N, 162.12773; found, 162.12815. [α]_D^{25} +13.84 (c 0.81, CHCl₃).

**Synthesis of N-heterocyclic six-membered ring compound (Figure 15a).**

To a solution of (S)-4da (133 mg, 0.5 mmol) in EtOH (5.0 mL) was added NaBH₄ (189 mg, 5.0 mmol). The reaction mixture was stirred at 60 °C for 12 h, quenched with water. The aqueous layer was extracted with EtOAc, and the combined organic layer was washed with water and brine, and was dried over anhydrous MgSO₄, filtered, and evaporated under reduced pressure to give secondary amine as a pale yellow oil (131 mg, 0.49 mmol) in 98% yield.

To a solution of the secondary amine (53.5 mg, 0.2 mmol) in DMF (0.8 mL) was added allylbromide (41.2 µL, 0.5 mmol) and K₂CO₃ (69.1 mg, 0.5 mmol) at room temperature. The reaction mixture was stirred at room temperature for 24 h, diluted with Et₂O and quenched with water. The aqueous layer was extracted with Et₂O, and the combined organic layer was washed with brine. The mixture was dried over anhydrous Na₂SO₄, filtered, and evaporated under reduced pressure. The residue was purified by flash column chromatography on silica gel (0–1% EtOAc/hexane) to give the allylamine (53.9 mg, 0.175 mmol) in 88% yield.

To a solution of the allylamine (23.6 mg, 76.0 µmol) in CH₂Cl₂ (760 µL) was added Grubbs-II catalyst (3.2 mg, 3.8 µmol) at room temperature. After being stirred at room temperature for 2 h, the reaction mixture was diluted with Et₂O. The mixture was filtrated through a short plug of silica gel with Et₂O as an eluent. The mixture was evaporated under reduced pressure. The residue was purified by flash column chromatography on silica gel (0–1% EtOAc/hexane) to give (S)-8a (19.5 mg, 70.0 µmol) in 92% yield. Pale Yellow Oil. IR (neat) 760, 818, 1038, 1242, 1509, 1458, 1581, 1601, 1663, 2965 cm⁻¹. ¹H NMR (400 MHz, CDCl₃) δ 1.52 (s, 3H), 3.19 (d, J = 12.4 Hz, 1H), 3.32 (d, J = 12.4 Hz, 1H), 3.62–3.64 (m, 2H), 3.74 (s, 3H), 5.87–5.96 (m, 2H), 6.74 (d, J = 9.2 Hz, 2H), 6.79 (d, J = 9.2 Hz, 2H), 7.20 (t, J = 7.6 Hz, 1H), 7.33 (t, J = 9.2 Hz, 2H), 7.45 (t, J = 9.2 Hz, 2H). ¹³C NMR (100 MHz, CDCl₃) δ 25.5, 41.4, 48.7, 55.6, 61.9, 114.4, 116.8, 124.0, 126.1, 126.6, 128.1, 134.1, 145.4, 146.9, 152.9. HRMS–ESI (m/z): [M+H]+ calcld for C₁₉H₂₂ON, 280.16759; found, 280.17010. [α]_D^{25} –97.03 (c 0.66, CHCl₃).

**Synthesis of allylic nitrile (Figure 15b).**

To a solution of (S)-5j (19.7 mg, 0.095 mmol) in EtOH (0.32 mL) was added NH₂OH•HCl (9.2 mg, 0.133 mmol) and NaOAc (11.7 mg, 0.143 mmol) at room temperature. The reaction mixture was stirred at room temperature for 2 h. After concentration of the reaction mixture in vacuo, Et₂O was added to the mixture. The organic layer was washed with water, dried over anhydrous MgSO₄, filtered, and evaporated under reduced pressure.

To a solution of the residue in THF (0.32 mL) was added 1,1’-carbonyldiimidazole (77.0 mg, 0.475 mmol). The reaction mixture was refluxed for 2 h and then cooled to 0 °C. The reaction
mixture was diluted with Et$_2$O and quenched with water at 0 °C. The aqueous layer was extracted with Et$_2$O, and the combined organic layer was washed with brine. The mixture was dried over anhydrous MgSO$_4$, filtered, and evaporated under reduced pressure. The residue was purified by flash column chromatography on silica gel (0–2% EtOAc/hexane) to give (S)-9j (16.6 mg, 0.08 mmol) in 84% yield. Pale Yellow Oil. IR (neat) 746, 930, 1131, 1410, 1456, 1600, 1637, 1724, 2236, 2986 cm$^{-1}$. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 1.92 (s, 3H), 5.38 (d, $J = 10.8$ Hz, 1H), 5.59 (d, $J = 17.6$, 1H), 6.04 (dd, $J = 17.6$ Hz, 10.8 Hz, 1H), 7.49–7.55 (m, 3H), 7.83–7.92 (m, 4H). $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 26.6, 44.6, 116.1, 121.8, 123.8, 124.7, 126.6, 126.7, 127.6, 128.1, 128.9, 132.7, 133.1, 136.6, 138.2. HRMS–APCI (m/z): [M+H]$^+$ calcd for C$_{15}$H$_{14}$N, 208.11208; found, 208.11227. 

$[^{[a]}^{}D_{26}$ –44.79 (c 0.90, CHCl$_3$).

Horner-Wadsworth-Emmons reaction (Figure 15c).

To a solution of (EtO)$_2$P(O)CH$_2$CO$_2$Et (40.5 µL, 0.2 mmol) and LiCl (8.5 mg, 0.2 mmol) in CH$_3$CN (0.5 mL) was dropped DBU (30.0 µL, 0.2 mmol) at room temperature and the reaction was stirred for 1 h at the same temperature. Next, (S)-5a (16.0 mg, 0.1 mmol) in CH$_3$CN (0.5 mL) was added dropwise over a period of 20 min at room temperature. After being stirred at room temperature for 4 h, the mixture was evaporated under reduced pressure. The residue was purified by flash column chromatography on silica gel (0–1% EtOAc/hexane) to give (R)-10a (19.5 mg, 0.85 mmol) in 85% yield. Pale Yellow Oil. IR (neat) 721, 764, 919, 990, 1030, 1165, 1277, 1649, 1717, 2979 cm$^{-1}$. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 1.29 (t, $J = 7.2$ Hz, 3H), 1.56 (s, 3H), 4.20 (q, $J = 7.2$ Hz, 2H), 5.06 (dd, $J = 17.6$, 1.2 Hz, 1H), 5.22 (dd, $J = 10.4$, 1.2 Hz, 1H), 5.79 (d, $J = 15.6$ Hz, 1H), 6.06 (dd, $J = 17.6$, 10.4 Hz, 1H), 7.17–7.35 (m, 6H). $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 14.2, 24.8, 47.9, 60.4, 114.2, 119.8, 126.7, 127.0, 128.4, 143.3, 144.4, 154.2, 166.8. HRMS–ESI (m/z): [M+Na]$^+$ calcd for C$_{15}$H$_{18}$O$_2$Na, 253.11990; found, 253.12027. [α]$_b$–26.45 (c 0.98, CHCl$_3$).

Synthesis of Chiral Naphthol-Carbene Ligand

The phenol- or naphthol-carbene ligands L1–5 were found in previous works of Sawamura and Ohmiya group and prepared according to the reported procedures. The synthesis of L1•HBF$_4$ is representative (Scheme 5). To a solution of Pd(db)$_2$ (575 mg, 1.0 mmol), rac-BINAP (770 mg, 1.2 mmol) and NaOttBu (1.98 g, 20.0 mmol) in toluene (30 mL) was added (1S,2S)-(-)-1,2-diphenylethlenediamine (11) (2.17 g, 10.0 mmol) and a solution of arylbromide 12 (3.69 g, 12.0 mmol) in toluene (20 mL). After being stirred at 100 °C for 24 h, the reaction mixture was filtered through a pad of celite, and the celite was washed with EtOAc. Solvent was removed under reduced pressure. The crude product was purified by column chromatography (silica gel,
5–45% EtOAc/hexane) to yield the coupling product 13 (3.07 g, 70%) as a brown solid. 13 was consistent with the literature data.8

To a solution of Pd(dba)2 (403 mg, 0.7 mmol), rac-BINAP (539 mg, 0.84 mmol) and NaOtBu (1.39 g, 14.0 mmol) in toluene (14 mL) was added amine 13 (3.07 g, 7.0 mmol) and a solution of 2-bromo-3,5-dicyclohexyltoluene33 [5.52 g, 14.0 mmol, containing 4-bromo-3,5-dicyclohexyltoluene (15%)] in toluene (14.0 mL). After being stirred at 130 °C for 48 h, the reaction mixture was filtered through a pad of celite, and the celite was washed with EtOAc. Solvent was removed under reduced pressure. The crude product was purified by column chromatography (silica gel, 0–1% EtOAc/hexane) to yield the coupling product 14 (3.6 g, 74%) as a white solid. 14 was consistent with the literature data.8

To a solution of 14 (3.6 g, 5.2 mmol) in MeOH/THF (11.1 mL/13.6 mL) was added HCl (4.0 M in dioxane, 6.5 mL, 26.0 mmol) at room temperature. After being stirr...
Scheme 4. The synthesis of \( L_1 \cdot \text{HBF}_4 \)

Acknowledgement

The studies described in this thesis have been carried out under the direction of Professor Masaya Sawamura at Graduate School of Chemical Sciences and Engineering, Hokkaido University from April 2012 to March 2018.

The author wishes to express his grateful acknowledgment to Professor Masaya Sawamura for giving opportunities to study in his laboratory and for his kind guidance, constant encouragement, and valuable discussion. He is deeply grateful to Professor Hirohisa Ohmiya for his practical guidance, helpful discussions and considerable suggestions. He would also like to express his appreciation to Assistant Professor Tomohiro Iwai and Assistant Professor Arteaga Arteaga Fernando for their kind discussions, advices and supports.

The author is much grateful to Professor Keiji Tanino, Professor Hajime Ito, Professor Hideaki Oikawa and Professor Tamaki Nakano for their accurate advices and considerable suggestions on this thesis.

A part of these studies was accomplished at Professor Ohmiya’s laboratory, Division of Pharmaceutical Sciences, Graduate School of Medical Sciences, Kanazawa University. The author would like to thank Professor Chisato Mukai, Associate professor Fuyuhiko Inagaki and Assistant Professor Shigeo Yasuda for valuable comments and discussions. He also expresses his thanks to all the members of Sawamura’s and Ohmiya’s group for their kind discussions. Especially, he would like to express his appreciation to co-workers Mr. Yoshinori Shido and Dr. Kazunori Nagao for excellent collaborations. He is also thankful to Mr. Masato Ueno for the excellent collaborations and the works not included on this thesis.

He is thanking truly to Professor Ruben Martin for giving him the opportunities to join his exciting research group at Institute of Chemical Research of Catalonia (ICIQ) from January to March in 2018. He is also thankful to all members in Professor Martin's research group for kind supports during my stay in ICIQ.

Financial support from JSPS, Research Fellowship of the Japan Society for the Promotion of Science for Young Scientists, was indispensible, and author deeply appreciates this support.

Finally, he would like to express his gratitude for his family, Mr. Shuji Hojoh and Ms. Yuko Hojoh for warm encouragement and continuous assistance.

Kentaro Hojoh
