Abstract. Rheumatoid arthritis (RA) is a commonly occurring autoimmune disease. Its defining pathological characteristic is the excessive proliferation of fibroblast-like synoviocytes (FLS), which is similar to tumor cells and results in a range of clinical problems. As a commonly used antipyretic, analgesic and anti-inflammatory drug, aspirin is the first-line treatment for RA. However, its mechanism of action has not been well explained. The goal is to investigate the biological effects of aspirin on primary RA-FLS and its underlying mechanisms. In this experiment we treated cells with various concentrations of aspirin (0, DMSO, 1, 2, 5, 10 mM). Cell proliferation activity was detected with CCK-8 assays. Apoptosis and cell cycle distribution were detected via flow cytometry. Apoptosis and cell cycle-associated proteins (Bcl-2, Bax, PRAP1, Cyclin D1, P21), as well as the key proteins and their phosphorylation levels of the NF-κB and JAK/STAT3 signaling pathways, were detected via western blot analysis. Bioinformatics prediction revealed that aspirin was closely associated with cell proliferation and apoptosis, including the p53 and NF-κB signaling pathways. By stimulating with aspirin, cell viability decreased, while the proportion of apoptotic cells increased, and the number of cells arrested in the G₀/G₁ phase increased in a dose-dependent manner. The expression of Bax increased with aspirin stimulation, while the levels of Bcl-2, PRAP1,

Cyclin D1 and P21 decreased; p-STAT3, p-P65 and p-50 levels also decreased while STAT3, P65, P50, p-P105 and P105 remained unchanged. From our data, it can be concluded that aspirin is able to promote apoptosis and inhibit the proliferation of RA-FLS through blocking the JAK/STAT3 and NF-κB signaling pathways.

Introduction

Rheumatoid arthritis (RA) is the most common chronic inflammatory joint disease, with a worldwide incidence of 0.5-1%. It is characterized by synovial inflammation of the joints. Repeated synovitis can cause joint pain, joint compulsion/stiffness and swelling, leading to the destruction of articular cartilage and bone. Furthermore, it may gradually cause joint deformity and dysfunction (1). Fibroblast-like synoviocytes (FLS) are an important component of the synovium and serve a major role in the pathological process of RA. One of the major pathological features of RA is the abnormal proliferation of FLS, manifesting as hyperplasia of synovial tissue (2). This is similar to the proliferation of tumor cells and is termed neoplastic. Reports showed that insufficient apoptosis and abnormal proliferation of FLS are observed in RA, and an excess of FLS lead to the various pathological processes of RA (3). Thus, promoting apoptosis of FLS and inhibiting proliferation is the primary focus of current studies surrounding RA treatment.

Aspirin is a nonsteroidal anti-inflammatory drug (NSAID), and is also known as acetylsalicylic acid (ASA). It functions as a cyclooxygenase (COX) inhibitor that has been widely used in anti-oxidation, anti-microbial and anti-inflammatory treatments, especially for RA. Aspirin has also been utilized for its function of anti-platelet aggregation and anti-inflammatory analgesia by inhibiting COX, which ultimately results in the decreased production of prostaglandins (4). In recent years, numerous studies have found that aspirin can also inhibit the proliferation of tumor cells and promote their apoptosis

Key words: aspirin, fibroblast-like synoviocytes, apoptosis, cell cycle, proliferation, NF-κB, JAK/STAT3

in a concentration- and time-dependent manner (5,6). These findings will be helpful in developing the wider use of aspirin and may explain, from a new perspective, the mechanism of aspirin as pertains to the treatment of RA.

STAT3 is an important transcription factor that is stimulated by exogenous signals such as IFN, IL-6 and other growth factors. The persistent activation of STAT3 can be detected in RA and the majority of tumor (7,8). Downstream targets of STAT3 are involved in cell proliferation, differentiation and apoptosis. It has also been shown that aberrant activation of STAT3 increases proliferation and tumorigenesis. The IL6/JAK/STAT3 pathway is also important in the pathogenesis of RA. NF- κ B is an intracellular transcription factor that controls and participates in cell growth, survival, apoptosis, inflammatory responses and oncogenesis. It not only serves an important role in the whole pathological process of RA, but also in the excessive proliferation and decreased apoptosis of RA-FLS (9).

So far, and to the best of our knowledge, there have been no reports on the direct effect of aspirin on RA-FLS and its potential mechanism. In our study, it was found that one of the ways in which aspirin functions is via promoting apoptosis as well as inhibiting proliferation of RA-FLS, in a dose-dependent manner. Thus, a possible mechanism has been proposed herein, by which aspirin functions to inhibit JAK/STAT3 and NF- κ B signaling pathways in RA-FLS.

Materials and methods

Drugs and reagents. Aspirin was purchased from Sigma-Aldrich (Merck KGaA, Darmstadt, Germany; A2093). It was dissolved in dimethyl sulfoxide (DMSO); the pH was adjusted to 7.0 by 1 mol/l NaOH and kept at -20°C for later use. Antibodies against Cyclin D1, P21, STAT3, p-STAT3, P50 were purchased from Abcam (Cambridge, UK). Secondary antibodies against GAPDH, Bax, PARP1 were from Proteintech Group (Wuhan, China). Bcl-2 was from Santa Cruz Biotechnology, Inc. (Dallas, TX, USA). P65, p-P65 were from Cell Signaling Technology, Inc. (Danvers, MA, USA). p-P50 was from Affinity Company (Changzhou, China).

Cell culture. Primary human RA-FLS were obtained from the BeNa Culture Collection Company (BNCC340230; Beijing, China). Dulbecco's modified Eagle's medium (DMEM), penicillin/streptomycin and fetal bovine serum (FBS) were purchased from Gibco (Thermo Fisher Scientific, Inc., Waltham, MA, USA). The cells were cultured in DMEM supplemented with 10% fetal bovine serum and 1% penicillin/streptomycin (penicillin: 10,000 U/ml, streptomycin: 10,000 μ g/ml), at 37°C in a humidified atmosphere of 95% air and 5% CO₂. In this experiment RA-FLS cells were treated with different concentrations of aspirin (0, DMSO, 1, 2, 5, 10 mM) *in vitro*.

Cell proliferation assay. The cells were harvested and then seeded in 96-well plates (1x10⁴ cells/well) with a total volume of 200 μ l culture medium. Cells were divided into 6 groups: Control group, DMSO-treated group and aspirin-treated groups (1, 2, 5 and 10 mM). Then, cells were incubated for 12, 24 and 48 h at 37°C. After the cells were treated for indicated

times, a Cell Counting Kit-8 (CCK-8; MedChem Express, China) was used (20 μ l per well) and cells were incubated for 3 h at 37°C. Subsequently, the plate absorbance was read using an automated microplate spectrophotometer (Bio-Rad Laboratories, Inc., Hercules, CA, USA) at 450 nm. Each experiment was repeated at least three times.

Cell apoptosis flow cytometry analysis. Aspirin-induced apoptosis was detected using an Annexin V-FITC Apoptosis Assay Kit (Hanbio, Shanghai, China). Treated cells (0, DMSO; 1, 2, 5 and 10 mM aspirin for 24 h) were harvested. Annexin V-FITC and propidium iodide (PI) were used based on the manufacturer's instructions. Annexin V specifically binds to the phosphatidyl serine (PS) residues on the cell membrane, and FITC is a marker of Annexin V; while PI binds to DNA once the cell membrane becomes permeable. The cells were stained, and the data were analyzed using BD Accuri C6 Plus (Becton-Dickinson, San Jose, CA, USA) software. Each experiment was repeated at least three times.

Cell cycle analysis. Cells were plated in parallel in 35-mm² culture plates at a concentration of 1x10⁶ cells/plate. After 24 h of serum starvation, cells were exposed to aspirin for various durations (0, DMSO; 1, 2, 5 and 10 mM) and then were harvested by trypsinization, washed twice in cool PBS and placed in 75% ethanol overnight at 4°C. Following this, cells were incubated in solution with the DNA-binding dye propidium iodide (PI) and RNase A (KeyGEN Biotech, Nanjing, China) for 30 min at 37°C in the dark. Finally, red fluorescence from 488 nm laser-excited PI in every cell was analyzed using a flow cytometer (Becton-Dickinson) using a peak fluorescence gate to discriminate aggregates. The percentage of cells in the G₀/G₁, S and G₂/M phases was determined from DNA content histograms created with BD Accuri C6 Plus software. Each experiment was repeated at least three times.

Western blot analysis. The 6 groups of cells (2x10⁶) were washed in PBS and then lysed with RIPA lysis buffer (Beyotime Institute of Biotechnology, Beijing, China). Cell debris was removed by centrifugation (Thermo Fisher Scientific, Inc.) at 10,000 x g for 15 min at 4°C, followed by protein concentration measurement using a BCA assay kit (Beyotime Institute of Biotechnology). Proteins were denatured by boiling for 5 min prior to electrophoresis, so that complete depolymerization of proteins could be achieved and a negative charge added; then, equivalent amounts of protein (30-40 μ g) samples were separated via 10-15% SDS-PAGE and transferred to immobilon polyvinylidene difluoride membranes. The membranes were blocked with 5% BSA in TBS-T for 1 h, and then incubated with rabbit anti-Bax (1:2,000 dilution, Proteintech Group; #S0599-2-Ig), anti-Bcl-2 (1:1,000 dilution, Santa Cruz Biotechnology, Inc.; #sc-7382), anti-PARP1 (1:2,000 dilution, Proteintech Group; #13371-1-AP), anti-P21 (1:1,000 dilution, #EPR3993), anti-cyclin D1 (1:10,000 dilution, #EPR2241; both from Abcam), anti-p65 (1:2,000 dilution; #8242), anti-p-P65 (1:2,000 dilution; #3033; both from Cell Signaling Technology, Inc.), anti-P50/P105 (1:1,000 dilution, Abcam; #E381), anti-p-P50/105 (1:1,000 dilution, Affinity Company; #AF3219), anti-STAT3 (1:2,000 dilution, #EPR787Y) and anti-p-STAT3

(1:200,000 dilution, #EP2147Y; both from Abcam) antibodies for 2 h at room temperature. The membranes were then washed three times with TBST for 10 min each time, and incubated with horseradish peroxidase-conjugated goat anti-rabbit secondary antibodies at a dilution of 1:5,000 for 1 h. After three washes with TBST, the immunoreactive bands were visualized using an ECL detection system (SmartChemi 420, Beijing, China). GAPDH served as the loading control. Each experiment was repeated at least three times.

Drug-target and direct protein targets (DPT)-associated genes search. The DrugBank 5.0.11 (<https://www.DrugBank.ca/>) is a database that collects detailed information about various drugs and associated materials (10). In the present study, 11 drug targets for aspirin were found using the DrugBank database. Information was collected on these 11 targets and the gene names entered into the 'Multiple Proteins by Names/Identifiers' search box in the STRING database (<https://STRING-db.org/cgi/input.pl>) (11) for primary DPT-associated genes. Parameters were set in minimum required interaction score: Highest confidence 0.900, then 300 secondary DPT-interacting proteins. Finally, 311 genes were collected, and data downloaded for the next analysis.

Network generation/visualization, founding hub gene and functional annotation. Associations between the 311 genes downloaded from the STRING database were identified using Cytoscape. APP-Cytohubba in Cytoscape was used to find the top 10 hub genes of the network by degree. The Database for

Annotation Visualization and Integrated Discovery (DAVID) online tool (<https://david.ncifcrf.gov/>) was used to conduct functional and pathway enrichment analyses in the present study (12,13). Additional GO and KEGG pathway enrichment analyses were performed to detect the potential biological functions and pathways of the 311 genes.

Statistical analysis. All experiments were performed at least three times, and the data (bar graphs) are presented as the means \pm standard deviations (SD). SPSS v.23.0 software (IBM Corp., Armonk, NY, USA) was used to analyze the data. One-way ANOVA was performed for multiple group comparisons, and the mean values of different groups were compared using the Student-Newman-Keuls (SNK) test. $P < 0.05$ was considered to indicate statistically significant differences.

Results

Visualization of aspirin-linkage networks by Cytoscape. Aspirin was input to DrugBank, which output DB00945-aspirin with 11 targets. Aspirin can inhibit PTGS1, PTGS2 and AKRIC1, activate PRKAA1, acetylate TP53, bind to HSPA5, and antagonize NF κ B2; the actions of EDNRA, IKBKB, RPS6KA3 and NF κ BIA were not mentioned but were closely associated with aspirin. Table I presents detailed information on the 11 primary DPTs of aspirin. Using the STRING database, a total of 300 proteins were identified that were associated with aspirin and its 11 primary DPTs, and a network of aspirin target-protein interactions was created (Fig. 1A). The

Figure 1. Network of drug-target genes and DPT-associated genes and their enrichment analysis. (A) DrugBank was used to find 11 primary and DPTs of aspirin (red); STRING was used to find 300 secondary DPT-interacting proteins (green); Cytoscape was used to create a PPI network of all 311 genes. (B) Cytohubba was used to find network hub genes by degree, and the top 10 hub genes are displayed (red, high score; yellow, low score). The second hub gene-UBC was not suitable as a hub gene, thus was removed. DPT, direct protein target; STRING, Search Tool for the Retrieval of Interacting Genes/Proteins; PPI, protein-protein interaction.

11 primary DPTs and their secondary DPT-associated proteins are presented in Fig. 1A. Next, Cytohubba in Cytoscape was used to analyze the top 10 hub genes in this network by degree, and these are as follows: TP53, UBC, EP300, RELA, AKT1, NFKB1, CDK2, MYC, CREBBP and NFKBIA (Fig. 1B).

The gene UBC encodes a ubiquitin precursor protein often found in the interactome database, as almost all proteins are ubiquitinated and degraded via the proteasome. Thus, it was considered that UBC is not a specific interaction hub molecule and was removed from the list of top 10 hub genes. The central

Figure 1. Continued. Network of drug-target genes and DPT-associated genes and their enrichment analysis. (C) DAVID was used to analyze GO annotations (biological process) of all 311 genes. The top 12 terms were selected according to P-value. (D) The top 12 KEGG pathways enriched for all 311 genes were identified using the aforementioned method. DAVID, Database for Annotation, Visualization and Integrated Discovery; KEGG, Kyoto Encyclopedia of Genes and Genomes; GO, gene ontology.

position of the TP53 gene suggests that it may largely be involved in the biological mechanism of aspirin.

Enrichment analysis of GO functions and pathways using DAVID. To assess the functional features of aspirin-mediated gene sets, GO annotations of all 311 genes were performed.

The top 12 terms were selected according to P-value. Top 12 KEGG pathways enrichment was also performed (Fig. 1C and D). A few interesting terms were selected interested us from the 12 KEGG terms and 12 GO (BP) terms (Table II). Functional analysis suggests that aspirin-associated genes are mainly linked to apoptosis and proliferation (cell cycle).

Table II. Notable pathway/biological process enrichment terms from the 12 significant KEGG/GO terms.

Figure 2. The CCK-8 assay results are presented as bar graphs for the antiproliferative effects of aspirin on RA-FLS. (A-C) RA-FLS were treated with (0, DMSO, 1, 2, 5 and 10 mM) aspirin for 12, 24 and 48 h. At each time interval, cell viability was determined by CCK-8 analysis. Data are presented as the means \pm SD (error bars) from three independent experiments. Aspirin inhibited the growth of RA-FLS in a dose-dependent manner. (D) Cell proliferation decreased at 12, 24 and 48 h. Data are presented as the means \pm SD (error bars) from three independent experiments. * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$ vs. DMSO group. CCK-8: Cell-Counting Kit-8; RA-FLS, rheumatoid arthritis-fibroblast-like synoviocytes; DMSO, dimethyl sulfoxide; SD, standard deviation.

Cytohubba results showed that TP53 serves the most important role in the network. Additionally, genes involved in the NF- κ B signaling pathway were revealed to be among the top 10 hub genes (Fig. 1B). The aforementioned evidence demonstrates a direct association of the biological effects of aspirin with the p53 axis and NF- κ B signaling pathway. Furthermore, aspirin can directly affect multiple key genes in the NF- κ B signaling pathway, including IKBKB, NFKBIA and NFKB2.

Aspirin inhibits RA-FLS cell proliferation. The effect of aspirin on cell proliferation was examined by using a CCK-8 to test cell viability. After administering aspirin, proliferation in each tested group was significantly and dose-dependently inhibited when compared with the control. Fig. 2A-C shows the effects of different concentrations of aspirin on cell viability at 12, 24 and 48 h. It was observed that cell viability gradually decreased with increasing concentrations of aspirin, and that DMSO had a slight effect on cell viability, but the effect is not statistically significant. Fig. 2D shows the percentage reduction in cell proliferation at each of the three time periods. These results indicate that aspirin can reduce cell viability and inhibit proliferation in a concentration-dependent manner.

Aspirin triggers RA-FLS cell apoptosis. An Annexin V-FITC/PI assay and flow cytometry were used to test the effects of aspirin on cell apoptosis. As described in Fig. 3A, the percentage of apoptotic cells in treated groups increased

gradually with the drug concentration. DMSO groups showed a slightly higher percentage of apoptosis than the control group, but this was not statistically significant. Fig. 3B shows a histogram of the apoptotic proportions in three independent experiments. These results suggest that aspirin can induce apoptosis in a concentration-dependent manner.

Aspirin induces cell cycle arrest at the G_0/G_1 phase and decreases the S phase fraction in RA-FLS. To further understand the role of aspirin in inhibiting proliferation and to explore its mechanism, flow cytometry was used to detect changes in cell cycle distribution. As presented in Fig. 4A, after aspirin administration, the S phase fraction decreased, while cells in the G_0/G_1 phase increased in a dose-dependent manner. Therefore, it is hypothesized that aspirin may arrest cells in the G_0/G_1 phase, preventing them from entering the S phase and thus decreasing proliferation.

Aspirin treatment regulates the expression of Bcl-2, Bax, PARP1, Cyclin D1 and P21 in RA-FLS. As indicated in Fig. 5, Bcl-2 levels decreased after the addition of aspirin, in a dose-dependent manner (Fig. 5A). Simultaneously, Bax levels increased with the addition of aspirin (Fig. 5A). Intracellular PARP1 content also decreased with increasing aspirin concentration (Fig. 5A). Cyclin D1, which promotes progression in the cell cycle, exhibited decreased intracellular levels after the addition of aspirin, in a concentration-dependent manner (Fig. 5A). P21 was also decreased after the addition of aspirin,

Figure 3. Aspirin induces apoptosis of RA-FLS. (A) Cells were exposed to various concentrations of aspirin for 24 h, and then harvested for apoptosis analysis via flow cytometry and Annexin V-FITC/PI assay. The figures show the apoptosis of RA-FLS induced by aspirin. (B) Bar graph showing the rates of RA-FLS apoptosis induced by various concentrations of aspirin for 24 h; this increased with higher concentrations of aspirin, thus is concentration-dependent. Data are presented as the means \pm SD (error bars) from three independent experiments. ** $P < 0.01$, *** $P < 0.001$ vs. DMSO group; FITC, fluorescein isothiocyanate; PI, propidium iodide; DMSO, dimethyl sulfoxide; RA-FLS, rheumatoid arthritis-fibroblast-like synoviocytes.

contrary to expectation (Fig. 5A). This suggests that P21 may not serve a role in this process. The results showed no significant differences between the DMSO and control groups. Fig. 5B depicts a bar graph with the gray value analysis for Bcl-2, Bax, PARP1, Cyclin D1 and P21.

Aspirin downregulates JAK/STAT3 and NF- κ B signaling by inhibiting STAT3 and P65, P50 phosphorylation in RA-FLS. Protein levels of STAT3, p-STAT3, P65, p-P65, P50, p-P50,

P105 and p-P105 were investigated via western blotting. It was observed that the JAK/STAT3 and NF- κ B signaling pathways were each inhibited after the addition of aspirin. p-P65, p-P50 and p-STAT3 levels decreased gradually with an increase in aspirin concentration, while the P65, P50, P105 and p-P105 levels were not affected (Fig. 6A). Fig. 6B depicts a bar graph representing protein expression. STAT3 was not affected, while p-STAT3 levels decreased (Fig. 7A); Fig. 7B shows the protein expression in a bar plot. This indicates that aspirin inhibits the

Figure 4. Graphs showing the effects of aspirin on cell cycle distribution in RA-FLS. (A) RA-FLS were treated with aspirin at various concentrations (0, DMSO; 1, 2, 5 and 10 mM) and the cell cycle distribution was detected by flow cytometry after 24 h. (B) Percentages of cells in the different phases are shown in the bar graph. With increased aspirin concentration, the number of cells in the G₀/G₁ phase increased while those in the S phase decreased. Aspirin blocks cells in the G₀/G₁ phase to prohibit progression into the S phase. Data are presented as the means \pm SD (error bars) from three independent experiments. *P<0.05, **P<0.01, ***P<0.001 vs. DMSO group. DMSO, dimethyl sulfoxide; RA-FLS, rheumatoid arthritis-fibroblast-like synoviocytes.

phosphorylation of P65, P50 and STAT3, thereby inhibiting JAK/STAT3 and NF- κ B signal transduction; this inhibitory effect of phosphorylation was concentration-dependent. The DMSO group was similar to the control, and the differences between them were not statistically significant.

Discussion

Aspirin and other NSAIDs are commonly used as anti-inflammatory and analgesic drugs (14). As research progresses, other functions of aspirin are being discovered,

such as its potential in cancer prevention (15,16). *In vivo*, low doses (75-150 mg/day) of aspirin can prevent and treat thrombosis, though higher doses of aspirin (3,000-6,000 mg/day) are required for treating RA. High doses of aspirin can cause serious side effects, while low doses may be less effective; reports have shown that for long-term use, 50-160 mg/day is optimal (17). *In vitro* experiments demonstrated that the maximum effective dose of aspirin varies between different cells, but generally remains in the 5-10 mM range; it may even reach 20 mM in cervical cancer cells (18). Therefore, four doses, 1, 2, 5 and 10 mM, were selected using the

Figure 5. Effects of aspirin on Bcl-2, BAX, PARP1, Cyclin D1 and P21 expression in RA-FLS. (A) After RA-FLS were exposed to various concentration of aspirin for 24 h, western blotting was used to determine Bcl-2, BAX, PARP1, Cyclin D1 and P21 protein levels. The corresponding internal control was GAPDH. Changes in Bcl-2, BAX, PARP1, Cyclin D1 and P21 protein expression in RA-FLS treated with aspirin are shown: Bcl-2, PARP1, Cyclin D1 and P21 were decreased while BAX was increased, each with increasing aspirin concentration. (B) Bar graph shows the gray value analysis of Bcl-2, BAX, PARP1, Cyclin D1 and P21. Data are presented as the means \pm SD (error bars) from three independent experiments. * P <0.05, ** P <0.01, *** P <0.001, **** P <0.0001 vs. DMSO group. We set the value as target protein vs. GAPDH, and set the value of control group as 1. CCND1, Cyclin D1; RA-FLS, rheumatoid arthritis-fibroblast-like synoviocytes; Bcl-2, B-cell lymphoma-2; BAX, Bcl-2-associated X protein; PARP1, poly (ADP-ribose) polymerase 1.

literature and preliminary experiments. The majority of *in vivo* experiments regarding aspirin in RA have been about its anti-inflammatory effects on FLS and immunocytes, resulting in a reduction in inflammatory factors (19). In RA, abnormal excessive inflammatory factors lead to abnormal FLS proliferation; aspirin has anti-inflammation effects that reduce these inflammation factors and block the associated

regulation of FLS, resulting in decreased abnormal proliferation. However, the direct effects of aspirin on FLS have not yet been studied, thus the current study aimed to investigate the antitumor effects of aspirin, particularly the mechanisms by which aspirin can inhibit proliferation and promote the apoptosis of multiple tumor cell types. Bioinformatics analyses were used to investigate biological processes and signaling

Figure 6. Effects of aspirin on the NF- κ B signaling pathway. It was observed that aspirin significantly affects the phosphorylation levels of P65 and P50. (A) Cells were treated with various concentrations of aspirin for 24 h, and then whole cell lysates were obtained and subjected to western blotting to detect p-P65, P65, p-P50, P50, p-P105 and P105. GAPDH served as the loading control. The levels of p-P65 and p-P50 decreased, whilst P65, P50, p-P105 and P105 remained the same. Phosphorylation of P65 and P50 was inhibited to varying degrees by aspirin. (B) Bar graph shows p-P65, P65, p-P50, P50, p-P105 and P105 protein expression, which was analyzed relative to GAPDH expression by densitometry. Data are presented as the means \pm SD (error bars) from three independent experiments. * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$, **** $P < 0.0001$ vs. the DMSO group. We set the value as target protein vs. GAPDH, and set the value of control group as 1. pathways in which aspirin is involved. Functional/activity network (FAN) analysis of gene-phenotype connectivity liaised by aspirin (20) was used, producing 10 genes: TP53, EP300, RELA, AKT1, NFKB1, CDK2, MYC, CREBBP and NFKBIA. Many of these genes are associated with cell proliferation and apoptosis. TP53 is an important gene involved in proliferation (21), indicating that aspirin affects cell proliferation (22). Furthermore, RELA, NFKB1 and NFKBIA are important molecules in the NF- κ B signaling pathway. Therefore, we hypothesized that the NF- κ B signaling pathway is significantly regulated by aspirin, which has been confirmed in multiple myeloma cells using *in vivo* and *in vitro* experiments (23). Enrichment analysis results revealed that many biological processes and pathways affected by aspirin are associated with cell proliferation (cell cycle) and apoptosis (Table II). These results indicate that aspirin has a significant regulatory effect on cell proliferation and apoptosis. In both GO (BP) and KEGG, signals associated with the NF- κ B cascade were evident, suggesting that aspirin may regulate cells through this pathway (24). According to these bioinformatics results, it was initially concluded that

aspirin is able to regulate cell proliferation and apoptosis, mainly through the p53 and NF- κ B signaling pathways (25).

FLS are similar to cancer cells without the restriction of excessive proliferation (26,27). Apoptotic defects are another important cause of synovial hyperproliferation (28). Aspirin is a first-line treatment drug in RA, working to prevent the conversion of arachidonic acid to prostaglandin by inhibiting COX (4). In other words, it serves the role of an anti-inflammatory analgesic drug. Among the emerging biotherapeutic approaches to RA is cell-based therapy, which targets synovial cells. Therefore, it is essential to understand whether and how aspirin is able to directly affect FLS. Data from the present study indicate that the activity of RA-FLS decreases significantly after the addition of aspirin. Decreased RA-FLS was also noted to persist as the concentration of aspirin increased, indicating it was concentration-dependent. This result is similar to the effect of aspirin on glandular tumors (29). Flow cytometry revealed that apoptosis occurred irrespective of aspirin use; however, after adding aspirin the degree of apoptosis increased. With increased aspirin concentration, the level of apoptosis increased relatively, regardless of whether cells were in the

Figure 7. Effects of aspirin on the JAK/STAT3 signaling pathway. Aspirin significantly affects the phosphorylation level of STAT3. (A) Cells were treated with various concentrations of aspirin for 24 h, after which whole cell lysates were obtained and subjected to western blotting to detect p-STAT3 and STAT3. GAPDH served as the loading control. Results showed a decrease in p-STAT3, whilst STAT3 remained unchanged. Phosphorylation of STAT3 was inhibited to varying degrees by aspirin. (B) Bar graph represents the expression of p-STAT3 and STAT3, which were analyzed relative to GAPDH expression by densitometry. Data are presented as the means \pm SD (error bars) from three independent experiments. * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$, **** $P < 0.0001$ vs. DMSO group. We set the value as target protein vs. GAPDH and set the value of control group as 1. RA-FLS, rheumatoid arthritis-fibroblast-like synoviocytes; STAT3, signal transducer and activator of transcription 3; DMSO, dimethyl sulfoxide; p-, phosphorylated.

early or late apoptotic stage. It was speculated that this effect is concentration-dependent. In colon cancer, aspirin can induce tumor cell apoptosis (30). There are two known pathways of apoptosis: The death receptor pathway and the intrinsic mitochondrial pathway. The intrinsic mitochondrial pathway is considered to be the more critical pathway of the two in terms of the mechanism of apoptosis (31-34). Mitochondrial pathway-mediated apoptosis is largely regulated by the Bcl-2 protein family. Bax exerts pro-apoptotic effects while Bcl-2 exerts inhibitory effects on apoptosis (33). In this study, the expression of Bax protein was significantly increased in FLS treated with aspirin, while the expression of Bcl-2 protein was significantly decreased. This resulted in an increased Bax/Bcl-2 protein ratio, which is observed in many other cell types during external stimulus-induced apoptosis (23). That aspirin treatment significantly increases the expression of PARP1 protein, relative to the control, suggests that aspirin-induced FLS apoptosis may be mediated by the caspase-mitochondrial apoptotic pathway.

We examined the distribution of the cell cycle by flow cytometry and the expression of cell cycle-associated proteins was measured via western blotting. According to the results, as aspirin concentration increased, the G_0/G_1 phase fraction increased, indicating that aspirin can prevent cells entering the S phase thus arresting cells in the G_0/G_1 phase and affecting proliferation (35). The molecular mechanisms of the cell cycle regulation involve cyclin, cyclin-dependent kinase (CDK) and CDK inhibitor (CKI) interactions (34,36). After adding aspirin, Cyclin D1 decreased in a concentration-dependent manner, demonstrating that aspirin causes cell cycle arrest in the G_0/G_1 phase, potentially via the regulation of Cyclin D1 affecting the normal cell cycle, thus inhibiting proliferation. This is similar to results obtained with numerous other tumor cell types (36). The P21 gene is a cyclin-dependent kinase inhibitor able to arrest cells in the G_1 phase (37-40). The results showing the gradual decrease of P21 following the addition of aspirin are inconsistent with our expectations, and contrary to those obtained from other experiments on inhibiting the cell cycle (29). Therefore, there are significant differences between cell types. We hypothesized that aspirin might inhibit the cell cycle in RA-FLS not through P21, but via other molecules such as P27, though further experiments are required for specificity and for verification.

The IL-6/JAK/STAT3 pathway serves a key role in RA (41); there are many genes regulating the cell cycle and

apoptosis downstream of the JAK/STAT3 pathway. Therefore, further study of JAK/STAT3 signaling pathway may reveal the mechanism of aspirin on FLS (41). In the present study, the content of STAT3 and p-STAT3 was compared using western blotting before and after the addition of aspirin, revealing that the content of STAT3 was not affected by the addition of aspirin though p-STAT3 levels decreased with increasing aspirin concentration. These results suggest that aspirin likely affects the phosphorylation of STAT3, leading to JAK/STAT3 signaling pathway inhibition. These results are concordant with those in other tumor cells, in which aspirin decreased STAT3 phosphorylation by blocking the formation of STAT3 phosphodiesterase (42). Aspirin inhibits the proliferation of RA-FLS and promotes apoptosis. This may be associated with blockade of the JAK/STAT3 signaling pathway, leading to decreased downstream anti-apoptotic and cell cycle regulatory gene expression.

The NF- κ B signaling pathway also serves a key role in the pathogenesis of RA. NF- κ B is an important nuclear transcription factor in the pathogenesis of RA, which has two principal mechanisms: Firstly, NF- κ B activation can increase the transcription of inflammatory mediators, and these inflammatory mediators can, in turn, activate NF- κ B expression; both constitute a positive feedback mechanism leading to the inflammatory response of RA (43). Secondly, it is able to block synovial cell apoptosis, resulting in synovial cell hyperplasia (44). The transcription factor NF- κ B regulates the expression of anti-apoptosis proteins and antagonizes the TNF-induced apoptosis of FLS (45). Studies have shown that aspirin can inhibit NF- κ B activity and prevent its transfer to the nucleus (46). According to previous bioinformatics results, aspirin may affect the NF- κ B signaling pathway by affecting P65 and P50. Our results showed that the content of P65, P50, P105 and p-P105 did not change after the addition of aspirin, while p-P65 and p-P50 levels gradually decreased with increased aspirin concentration. This indicates that aspirin affects P65 and P50 phosphorylation, resulting in NF- κ B pathway inhibition. There are anti-apoptotic genes and cell cycle-promoting genes downstream of the NF- κ B pathway (47); therefore, it may be considered that aspirin can inhibit the phosphorylation of P65 and P50 to inhibit NF- κ B, thus affecting apoptosis and proliferation. This is consistent with results obtained in osteoclast cells (48).

In summary, our results indicate that aspirin is capable of promoting apoptosis in RA-FLS, and of inhibiting proliferation by blocking the cell cycle, in a concentration-dependent manner. Aspirin was found to reduce STAT3, P65 and P50 phosphorylation, thereby inhibiting the JAK/STAT3 and NF- κ B signaling pathways. Aspirin promoting apoptosis and inhibiting proliferation may be achieved by blocking both pathways. This direct effect of aspirin on RA-FLS, which has not been previously reported to the best of our knowledge, may provide a novel perspective for revealing the underlying molecular mechanisms and exploring new therapeutic targets for RA. However, many problems remain unsolved that require further study, including the *in vivo* effects of aspirin on FLS for which we intend to use an RA rat model to investigate.
