Low-melting oxide glasses are promising as electrolytes for all-solid-state lithium rechargeable batteries. Glasses in the pseudobinary system  $\text{Li}_3\text{BO}_3\text{--Li}_2\text{SO}_4$  were prepared by a mechanochemical technique. Raman spectra revealed that the glasses contained no macroanions which form networks but consisted only of  $\text{Li}^+$  ions and two discrete ortho-oxoanions,  $\text{BO}_3^{3-}$  and  $\text{SO}_4^{2-}$ . The density and molar volume increased and elastic moduli decreased with an increase in the  $\text{Li}_2\text{SO}_4$  content in the glasses. The heat treatment of the  $\text{Li}_3\text{BO}_3\text{--Li}_2\text{SO}_4$  glasses at around  $300^\circ\text{C}$  brought about the crystallization to form ion conducting glass-ceramics. Electrical conductivities of the glasses and glass-ceramics in this system were maximized with the mixing of  $\text{Li}_3\text{BO}_3$  and  $\text{Li}_2\text{SO}_4$ . The conductivities were higher in the glass-ceramics of the compositions with small amounts of  $\text{Li}_2\text{SO}_4$ , ranging from  $3 \times 10^{-6}$  to  $1 \times 10^{-5} \text{ S cm}^{-1}$  at room temperature, compared to the corresponding glasses. This conductivity enhancement by the heat treatment is probably due to the precipitation of solid solutions with a high temperature  $\text{Li}_3\text{BO}_3$  phase.

Key-words : Solid electrolyte, Ionic glass, Glass-ceramic, All-solid-state battery

[Received February 13, 2017; Accepted March 28, 2017]

## 1. Introduction

Glass-based solid electrolytes with high lithium-ion conductivity have been gaining much attention because of their potential application to safe and reliable all-solid-state lithium rechargeable batteries.<sup>1)</sup> Sulfide glasses<sup>2)</sup> and glass-ceramics<sup>3,4)</sup> are promising for these batteries because of their high ionic conductivities around  $10^{-2} \text{ S cm}^{-1}$  at room temperature<sup>4)</sup> comparable to organic liquid electrolytes and superionic sulfide crystals.<sup>5)</sup> Sulfide glass-based electrolytes have a great advantage in achieving close solid/solid contacts by just a cold-press without high-temperature sintering because of their excellent formability at room temperature.<sup>6)</sup> A disadvantage of sulfide electrolytes is their instability under regular air atmosphere with moisture. Oxide-based solid electrolytes, on the other hand, are favorable for battery application because of their high stability in air atmosphere with no possibility of  $\text{H}_2\text{S}$  gas generation from the electrolytes. However, it is very hard to use oxide solid electrolytes in all-solid-state batteries mainly because they have quite poor deformability at room temperature, and thus there remains large interfacial resistance between electrolytes and electrodes.<sup>6)</sup> A sintering process of oxide electrolytes at high temperatures sometimes causes chemical reactions at the interface between electrolytes and electrodes to cause the large interfacial resistances. To obtain excellent oxide solid electrolytes suitable for application in all-solid-state rechargeable batteries, “low melting” is one of the most important properties.

A series of mixed-former glasses with high lithium ion conductivity were reported in lithium ortho-oxosalt pseudobinary

systems such as  $\text{Li}_4\text{SiO}_4\text{--Li}_3\text{BO}_3$ .<sup>7)</sup> Various kinds of mixed-former “ion glasses” as oxide solid electrolytes were developed by using rapid melt-quenching and mechanochemical techniques.<sup>8,9)</sup> The  $\text{Li}_3\text{BO}_3\text{--Li}_2\text{SO}_4$  glassy system, one of these ion glass systems, is most attractive in the sense of low melting character. In addition, since both  $\text{Li}_3\text{BO}_3$  and  $\text{Li}_2\text{SO}_4$  have superionic high-temperature phases,<sup>10,11)</sup> these superionic phases could precipitate during glass heating to obtain highly conductive glass-ceramic electrolytes.<sup>3)</sup> So we tried to evaluate the possibility of the  $\text{Li}_3\text{BO}_3\text{--Li}_2\text{SO}_4$  glass and glass-ceramic materials as an excellent oxide solid electrolyte for the application to all-oxide battery systems.

Recently we have successfully prepared highly conductive and low-temperature deforming  $\text{Li}_{2.9}\text{B}_{0.9}\text{S}_{0.1}\text{O}_{3.1}$  ( $90\text{Li}_3\text{BO}_3 \cdot 10\text{Li}_2\text{SO}_4$  in mol %) glass-ceramics.<sup>12)</sup> Our previous paper mainly reported the characterization and the application of these newly obtained glass-ceramics to oxide-based all-solid-state lithium secondary batteries using conventional electrode active materials.<sup>12)</sup> The present paper reports physicochemical properties and structure of the mechanochemically prepared  $\text{Li}_3\text{BO}_3\text{--Li}_2\text{SO}_4$  glasses. Mechanical, electrical and thermal properties and densities were examined for the binary glasses in a wide range of composition. The formation and characterization of heat-treated glass-ceramics were done on the basis of the diffraction and conductivity measurements.

## 2. Experimental

The  $\text{Li}_3\text{BO}_3\text{--Li}_2\text{SO}_4$  glasses were prepared by a mechanochemical technique using  $\text{Li}_3\text{BO}_3$  and  $\text{Li}_2\text{SO}_4$  crystals. The  $\text{Li}_3\text{BO}_3$  crystal was prepared by heating a mixture of  $\text{LiOH} \cdot \text{H}_2\text{O}$  (>99%; Wako Chem.) and  $\text{H}_3\text{BO}_3$  (>99%; Wako Chem.) at  $500^\circ\text{C}$  for 1 h and then sintering the product at  $600^\circ\text{C}$  for 2 h in

<sup>†</sup> Corresponding author: M. Tatsumisago; E-mail: tatsu@chem.osakafu-u.ac.jp

air. The  $\text{Li}_2\text{SO}_4$  crystal was prepared by heating  $\text{Li}_2\text{SO}_4 \cdot \text{H}_2\text{O}$  (>99%; Aldrich Chem.) at 300°C for 2 h under Ar atmosphere. A mixture of the crystals of  $\text{Li}_3\text{BO}_3$  and  $\text{Li}_2\text{SO}_4$  was put into a 45 ml  $\text{ZrO}_2$  pot with 500  $\text{ZrO}_2$  balls (5 mm in diameter) and milled at the rotating speed of 370 rpm and the milling periods of 40–144 h. A planetary ball mill apparatus (Pulverisette 7, Fritsch GmbH) was used. All processes were conducted in a dry Ar atmosphere. Glass-ceramic samples were prepared by heating the glass samples.

X-ray diffraction (XRD) measurements ( $\text{Cu K}\alpha$ ) were conducted using a diffractometer (SmartLab, Rigaku Corp.) to identify crystal phases of the glass samples and the glass-ceramic samples. Differential thermal analyses (DTA) were performed using a thermal analyzer (Thermo-plus 8120, Rigaku Corp.) to observe glass-transition, crystallization and melting temperatures. The mechanochemically prepared samples, which were sealed in Al pans in an Ar-filled glove box, were heated at  $10^\circ\text{C min}^{-1}$  under  $\text{N}_2$  gas flow up to 900°C. Raman spectra were recorded using a Raman spectrophotometer (LabRam HR-800, HORIBA Jobin Yvon) with 325 nm He–Cd laser.

Bulk densities of the powder-compressed pellets were calculated from the weight and volume of the pellets and relative densities were calculated by dividing the bulk density of the pellet by the apparent density of the obtained powder determined by an Ar gas pycnometer (AccuPyc II 1340, Shimadzu).

The elastic moduli were evaluated for the hot-pressed glass pellets by the ultrasonic pulse-echo technique using 5 MHz frequency transducers (5077PR, Olympus). Hot-pressed pellets were prepared by pelletizing the glass powders at 360 MPa at around each glass-transition temperature for 4 h in an Ar-filled glove box. The thickness and diameter of the prepared pellets were about 2 and 10 mm, respectively.

Electrical conductivities were measured for the samples pelletized under 720 MPa at room temperature. The pellets were 10 mm in diameter and about 1.5 mm in thickness. Gold electrode was deposited on both faces of the pellets by using a sputter apparatus (Quick Coater SC-701, Sanyu electron Corp.). Then stainless steel disks were attached to the pellets as current collectors. The prepared cell was sealed in a silica glass tube. Then AC impedance measurements were conducted under dry Ar gas flow using an impedance analyzer (SI-1260; Solartron analytical). The frequency range was 10 Hz to 8 MHz and the applied voltage was 50 mV. The AC impedance measurements were conducted at 25°C for the glass samples. Then the pellets were heated to above the crystallization temperatures to obtain glass-ceramics. The impedances of glass-ceramic samples were measured after cooling the pellets to 25°C. All the structural analyses and conductivity measurements were done in a dry Ar atmosphere without air exposure of the samples.

### 3. Results and discussion

The glass-forming region by twin-roller melt quenching was already reported for the pseudobinary system  $\text{Li}_3\text{BO}_3\text{--Li}_2\text{SO}_4$ .<sup>8)</sup> Glass formation by the mechanochemical technique was tried for  $x = 0, 10, 25, 50, 60, 70, 80$  and 90 of  $(100 - x)\text{Li}_3\text{BO}_3 \cdot x\text{Li}_2\text{SO}_4$ ; all the compositions are the nominal ones. **Figure 1** shows the XRD patterns of the  $\text{Li}_3\text{BO}_3\text{--Li}_2\text{SO}_4$  samples prepared by the mechanochemical technique for appropriate ball-milling periods of time; the milling period for each sample denoted in the figure was determined as an enough time to observe no diffraction peaks of starting materials. Halo patterns typical in amorphous materials are observed up to  $x = 80$  prepared by 40–110 h milling of the mixture of  $\text{Li}_3\text{BO}_3$  and  $\text{Li}_2\text{SO}_4$  crystals, suggesting a very large

Fig. 1. XRD patterns of mechanochemically prepared  $(100 - x)\text{Li}_3\text{BO}_3 \cdot x\text{Li}_2\text{SO}_4$  samples and  $\text{Li}_2\text{SO}_4$  crystal. Milling periods of time for each sample are noted in the bracket.

Fig. 2. DTA curves of the mechanochemically prepared  $(100 - x)\text{Li}_3\text{BO}_3 \cdot x\text{Li}_2\text{SO}_4$  samples and  $\text{Li}_2\text{SO}_4$  crystal.

glass-forming region in this system also in the case of mechanochemical process. The pattern of the  $x = 90$  sample is similar to that of a high temperature phase,  $\alpha\text{-Li}_2\text{SO}_4$  (JCPDS#073-6539); somewhat peak shift to the higher angle side was observed and thus a  $\alpha\text{-Li}_2\text{SO}_4$ -based solid-solution with  $\text{Li}_3\text{BO}_3$  is formed at the composition.

**Figure 2** shows the DTA curves of the  $(100 - x)\text{Li}_3\text{BO}_3 \cdot x\text{Li}_2\text{SO}_4$  ( $x = 0, 5, 10, 15, 25, 50, 60, 70, 80$  and 90) samples prepared by the mechanochemical technique and crystalline  $\text{Li}_2\text{SO}_4$  ( $x = 100$ ). Since the amorphous samples tend to show small endothermic shifts typical of glass transition, these amorphous samples with  $x = 0\text{--}80$  are considered as glassy materials. These glasses with  $x = 0\text{--}70$  exhibit very sharp exothermic peaks. These exotherms are due to crystallization of these glasses because crystalline products are obtained after the heat treatments at temperatures beyond these exothermic peaks as shown later in **Fig. 6**.

**Figure 3** shows the Raman spectra of mechanochemically prepared  $\text{Li}_3\text{BO}_3\text{-Li}_2\text{SO}_4$  glasses. The  $\text{Li}_3\text{BO}_3$  glass exhibits an intense band at around  $930\text{ cm}^{-1}$ , which is assigned to the stretching mode of orthoborate  $\text{BO}_3^{3-}$  ions.<sup>13)</sup> The  $\text{Li}_2\text{SO}_4$  crystal exhibits an intense band at around  $1010\text{ cm}^{-1}$ , which is assigned to the stretching mode of sulfate  $\text{SO}_4^{2-}$  ions.<sup>14)</sup> The glasses containing both  $\text{Li}_3\text{BO}_3$  and  $\text{Li}_2\text{SO}_4$  show two bands near  $930$  and  $1010\text{ cm}^{-1}$ . The  $930\text{ cm}^{-1}$  band is weakened and the  $1010\text{ cm}^{-1}$  band is strengthened with increasing the  $\text{Li}_2\text{SO}_4$  content. Since there are no marked Raman bands other than these in any glass, these glasses contain no macroanions forming networks and consist only of  $\text{Li}^+$  ions and discrete  $\text{BO}_3^{3-}$  and  $\text{SO}_4^{2-}$  ions. These glasses thus can be called as “ion glasses”.

Fig. 3. Raman spectra of mechanochemically prepared  $(100-x)\text{-Li}_3\text{BO}_3\cdot x\text{Li}_2\text{SO}_4$  samples and  $\text{Li}_2\text{SO}_4$  crystal.

Fig. 4. Dependence of apparent density and molar volume on the  $\text{Li}_2\text{SO}_4$  content of the  $(100-x)\text{Li}_3\text{BO}_3\cdot x\text{Li}_2\text{SO}_4$  glasses.

**Figure 4** shows the relationship between the apparent density of the obtained glass powder and the  $\text{Li}_2\text{SO}_4$  content in the system  $(100-x)\text{Li}_3\text{BO}_3\cdot x\text{Li}_2\text{SO}_4$ . The density as well as its molar volume increases with increasing the  $\text{Li}_2\text{SO}_4$  content, indicating that the addition of  $\text{Li}_2\text{SO}_4$  instead of  $\text{Li}_3\text{BO}_3$  brings a volume increase of the glass. The  $(100-x)\text{Li}_3\text{BO}_3\cdot x\text{Li}_2\text{SO}_4$  glass powders were cold-pressed at  $360\text{ MPa}$  and their relative densities were calculated. **Figure 5(a)** shows that with increasing the  $\text{Li}_2\text{SO}_4$  content, the relative density increases linearly. Cross-sectional SEM images of the  $\text{Li}_3\text{BO}_3$  ( $x=0$ ) and  $20\text{Li}_3\text{BO}_3\cdot 80\text{Li}_2\text{SO}_4$  ( $x=80$ ) glasses as shown in Figs. 5(b) and 5(c) also suggest that the glass is densified with the addition of  $\text{Li}_2\text{SO}_4$ . This change is probably brought by a larger molar volume of the glass with a higher amount of  $\text{Li}_2\text{SO}_4$ .

The  $(100-x)\text{Li}_3\text{BO}_3\cdot x\text{Li}_2\text{SO}_4$  glasses were hot-pressed at around each glass-transition temperature to prepare further densified pellets and examine their elastic properties. The ultrasonic pulse-echo measurements were conducted for the hot-pressed pellets with the relative densities of 92–96% and the results are summarized in **Table 1**. The elastic moduli are roughly decreased with increasing the  $\text{Li}_2\text{SO}_4$  content. This might be related to the molar volume of the glass. In typical oxide glasses, the elastic moduli decrease with increasing their mean atomic volumes.<sup>15)</sup> Thus, the larger molar volume with increasing the  $\text{Li}_2\text{SO}_4$  content (see Fig. 5) mainly contributes to the elastic modulus change.

**Figure 6** shows the XRD patterns of the heat-treated  $\text{Li}_3\text{BO}_3\text{-Li}_2\text{SO}_4$  glasses; the heat-treatment temperatures, ranging from  $250$  to  $290^\circ\text{C}$ , are just after the first sharp exothermic peaks in Fig. 2. The XRD patterns of the samples from  $x=5\text{--}25$  are attributable to solid solution phases of high temperature phase of  $\text{Li}_3\text{BO}_3$  and  $\text{Li}_2\text{SO}_4$ . These phases are probably precipitated only from glass as metastable ones. In Fig. 2, several exothermic and endothermic peaks other than the first exothermic peaks due to crystallization are observed in the temperature range  $300\text{--}900^\circ\text{C}$ .

Fig. 5. (a) Relative density of the  $(100-x)\text{Li}_3\text{BO}_3\cdot x\text{Li}_2\text{SO}_4$  glasses cold-pressed at  $360\text{ MPa}$ . Cross-sectional SEM images of the (b)  $\text{Li}_3\text{BO}_3$  ( $x=0$ ) and (c)  $20\text{Li}_3\text{BO}_3\cdot 80\text{Li}_2\text{SO}_4$  glasses.

Table 1. Molding temperature, bulk density, relative density, longitudinal velocity ( $V_L$ ), shear velocity ( $V_S$ ), shear modulus ( $G$ ), Young’s modulus ( $E$ ), bulk modulus ( $K$ ) and Poisson’s ratio ( $\nu$ ) of the  $(100-x)\text{Li}_3\text{BO}_3\cdot x\text{Li}_2\text{SO}_4$  glasses

Composition	Molding temperature / $^\circ\text{C}$	Bulk density / $\text{g cm}^{-3}$	Relative density / %	$V_L$ / $\text{m s}^{-1}$	$V_S$ / $\text{m s}^{-1}$	$G$ / $\text{GPa}$	$E$ / $\text{GPa}$	$K$ / $\text{GPa}$	$\nu$
$90\text{Li}_3\text{BO}_3\cdot 10\text{Li}_2\text{SO}_4$	240	1.92	91.8	6980	3180	19.4	53.1	67.6	0.37
$40\text{Li}_3\text{BO}_3\cdot 60\text{Li}_2\text{SO}_4$	195	2.10	94.7	5760	2830	16.8	45.0	47.2	0.34
$30\text{Li}_3\text{BO}_3\cdot 70\text{Li}_2\text{SO}_4$	160	2.13	95.7	6040	2820	17.0	46.2	55.2	0.36
$20\text{Li}_3\text{BO}_3\cdot 80\text{Li}_2\text{SO}_4$	105	2.07	92.3	5530	2400	11.9	33.0	47.4	0.38

Fig. 6. XRD patterns of the heat-treated  $(100-x)\text{Li}_3\text{BO}_3 \cdot x\text{Li}_2\text{SO}_4$  glasses (glass-ceramics).

Fig. 7. Relationship between melting point and the  $\text{Li}_2\text{SO}_4$  content in the  $(100-x)\text{Li}_3\text{BO}_3 \cdot x\text{Li}_2\text{SO}_4$  samples.

Fig. 8. Complex impedance plots of the  $(100-x)\text{Li}_3\text{BO}_3 \cdot x\text{Li}_2\text{SO}_4$  glasses at room temperature.

These DTA and XRD data suggest that the  $\text{Li}_3\text{BO}_3$  crystal exhibit the melting temperature of  $820^\circ\text{C}$  and the liquidus temperature decreases from  $820$  to  $630^\circ\text{C}$  with increasing  $x$  from  $0$  to  $70$ . Further increase of  $x$  increases the liquidus temperature toward the melting temperature of  $\text{Li}_2\text{SO}_4$ . **Figure 7** shows the relationship between melting point and the  $\text{Li}_2\text{SO}_4$  content in the  $(100-x)\text{Li}_3\text{BO}_3 \cdot x\text{Li}_2\text{SO}_4$  samples. An eutectic composition should be around  $x = 70$  and the eutectic temperature around  $630^\circ\text{C}$ .

**Figure 8** shows the results of the complex impedance measurements of the  $\text{Li}_3\text{BO}_3\text{--Li}_2\text{SO}_4$  glasses at room temperature as

Fig. 9. Temperature dependence of electrical conductivity for the  $90\text{Li}_3\text{BO}_3 \cdot 10\text{Li}_2\text{SO}_4$  ( $x = 10$ ) glass and glass-ceramic.

Fig. 10. Composition dependence of electrical conductivity at room temperature for the  $(100-x)\text{Li}_3\text{BO}_3 \cdot x\text{Li}_2\text{SO}_4$  glasses and glass-ceramics.

examples. These data were obtained for the glass powder-compressed pellets with blocking electrodes. The total impedance including bulk and grain boundary is attributed to the semicircle observed in all the glasses. The total resistance was obtained from the intersecting point of the semicircle with the real axis.

**Figure 9** shows examples of the temperature dependence of electrical conductivity for the mechanochemically prepared  $90\text{Li}_3\text{BO}_3 \cdot 10\text{Li}_2\text{SO}_4$  ( $x = 10$ ) glass and the corresponding heat-treated sample ( $290^\circ\text{C}$ ), which is called as “glass-ceramic”. The data are a good fit to the Arrhenius type equation. The conductivity at room temperature of the  $90\text{Li}_3\text{BO}_3 \cdot 10\text{Li}_2\text{SO}_4$  glass-ceramic is one order of magnitude higher than that of corresponding glass. The activation energies for the glass and the glass-ceramic are calculated as  $56$  and  $47 \text{ kJ mol}^{-1}$ , respectively.

**Figure 10** shows the composition dependence of ionic conductivity at room temperature for the cold-pressed  $\text{Li}_3\text{BO}_3\text{--Li}_2\text{SO}_4$  glasses and glass-ceramics. The conductivity values of  $\text{Li}_3\text{BO}_3\text{--Li}_2\text{SO}_4$  glasses range  $10^{-7}$ – $10^{-6} \text{ S cm}^{-1}$  in whole the composition range. The increase of conductivity is observed with the addition of small amounts of  $\text{Li}_2\text{SO}_4$ . This would be due to the improvement of relative density of the cold-pressed pellet (see Fig. 5) in addition to the so-called “mixed-former effect”.<sup>16)</sup> Both effects of the relative density and the mixed-former probably come from the anion mixing in the glasses.

The glass-ceramics exhibits much higher room temperature conductivities around  $10^{-5} \text{ S cm}^{-1}$  with the composition range with  $5 \leq x \leq 15$  compared to the corresponding glasses. Such a conductivity enhancement is attributable to the fact that the metastable solid solution phases of high temperature phase of  $\text{Li}_3\text{BO}_3$  and  $\text{Li}_2\text{SO}_4$ <sup>12)</sup> were precipitated in these glass-ceramic materials

as already shown in Fig. 6. The disappearance of the metastable phase at the compositions with  $x \geq 50$  largely decreases the conductivity. Structural analyses of the metastable phases are important to determine the origin of the high conductivity of these glass-ceramics, and further investigation is needed to improve ionic conductivity of this type of oxides as high as that of sulfide-based solid electrolytes.

#### 4. Conclusions

Low melting glasses in the system  $\text{Li}_3\text{BO}_3\text{--Li}_2\text{SO}_4$  were obtained by the mechanochemical technique. These glasses had no network structure but consisted only of  $\text{Li}^+$  ions and two discrete ortho-oxoanions of  $\text{BO}_3^{3-}$  and  $\text{SO}_4^{2-}$ ; such glasses can be called “ion glass”. The density and molar volume increased and elastic moduli decreased with an increase in the  $\text{Li}_2\text{SO}_4$  content in the glasses. Ionic conductivity of the glasses was increased with an addition of small amounts of  $\text{Li}_2\text{SO}_4$  to  $\text{Li}_3\text{BO}_3$  in this system, which is probably due to the mixed-former effect and/or the improvement of relative density of the cold-pressed pellet. Highly conductive glass-ceramics were obtained by the heat treatment of the  $\text{Li}_3\text{BO}_3\text{--Li}_2\text{SO}_4$  glasses, and exhibited higher ionic conductivities of about  $10^{-5} \text{ S cm}^{-1}$  at room temperature compared to the corresponding glasses. This conductivity enhancement by the heat treatment is probably due to the precipitation of solid solution phases with high temperature form of  $\text{Li}_3\text{BO}_3$ . Since the obtained glass-ceramics are low-melting, easily deformed and lithium ion conductive, these new “ion glass-ceramic” oxide electrolytes are promising for the application in all-solid-state oxide-based lithium batteries with high safety, reliability and stability.
