Abstract Palladium-catalyzed germylation of aryl bromides and aryl triflates using commercially available hexamethyldigermane is described. Optimized reaction conditions afforded various functionalized aryltrimethylgermanes, including drug-like molecules, in moderate to good yield, demonstrating the versatility of the presented protocols.

Key words palladium catalysis, germylation, digermane, aryl bromide, aryl triflate

Organosilicon¹ and organotin² compounds are useful reagents in organic synthesis and can be applied to a variety of synthetic transformations, including transition metal-catalyzed cross-coupling reactions. Organogermanium compounds, however, have attracted much less attention. Germanium is located between silicon and tin in the periodic table, and the properties of a C-Ge bond are intermediate between a C-Si bond and a C-Sn bond.³ Arylgermanes are expected to be more reactive toward electrophiles⁴ than arylsilanes due to the stronger β -effect from the C-Ge bond compared with the C-Si bond.⁵ Organotin compounds are more reactive, but highly toxic.⁶ Therefore, arylgermanes are potentially attractive synthetic intermediates, but only a limited number of synthetic reactions using arylgermanes are reported.^{3,4b-d,7,8} This is in part due to the high cost of germanium, but the lack of the general methods to prepare arylgermanes is also an important issue. Nucleophilic substitution of halogermanes by aryllithium or Grignard reagents is the most reliable method for accessing arylgermanes.^{3b} These highly reactive organometallic reagents are, however, incompatible with sensitive functional groups.

Transition metal-catalyzed silylation of aryl (pseudo)halides using disilanes⁹ or hydrosilanes¹⁰ has been extensively investigated over the last several decades for synthesizing

Figure 1 Germylation of aryl (pseudo)halides

arylsilanes without using aryllithium or Grignard reagents. On the other hand, studies of transition metal-catalyzed germylation of aryl halides are scarce,^{8c,9b,10h,k,11} although such reactions enable the direct synthesis of functionalized arylgermanes. Oshima achieved Pd-catalyzed germylation of aryl iodides using tri(2-furyl)germane, (Figure 1a),^{8c} but electron-deficient aryl iodides were not investigated, and an aryl bromide was unreactive. Yamanai and Nishihara reported general conditions for Pd-catalyzed coupling reactions of various aryl iodides and hydrogermanes (Figure 1a).^{10k} In contrast to aryl iodides, less reactive aryl bromides are still

^e PPh₃ (0.02 mmol, 20 mol %) was used as a ligand instead of **5**.

difficult substrates for germylation (Figure 1b). Earborn reported Pd-catalyzed germylation of aryl bromides with hexamethyldigermene, but the reactions required harsh conditions (140–180 °C) and resulted in a low yield.^{9b} Tanaka reported Pd-catalyzed germylation of bromobenzene and 2,5-dibromothiophene, but moisture sensitive dichlorotetramethyldigermene was required, and the results were rather complicated due to halogen exchange.¹¹ To date, general and practical conditions for transition metal-catalyzed germylation of aryl bromides and aryl triflates have not been reported.

In this article, we report Pd-catalyzed germylation of aryl bromides **1** and aryl triflates **2** using commercially available hexamethyldigermene **3** (Figure 1c).

We initiated our investigation by optimizing the reaction conditions for germylation of aryl bromide **1a** using hexamethyldigermene **3** (Table 1, entries 1–10). We selected the reaction conditions of Pd-catalyzed silylation of aryl halides with hexamethyldisilane reported by Shirakawa and Hiyama^{9a} as the initial conditions (entries 1,2). These conditions afforded the desired germylated arene **4a** in moderate yield along with several byproducts. GC/MS analysis revealed the formation of

reduced product **6**, biaryl **7**, and unidentified products bearing an allyl or propenyl group. We next investigated other palladium sources using toluene/H₂O as the solvent to circumvent incorporation of the C3 units derived from [PdCl(allyl)]₂. While Pd₂(dba)₃ exhibited inferior catalytic activity (entry 3), the use of Pd(OAc)₂ resulted in 62% yield (entry 4). In these cases, incorporation of the C3 unit was avoided, but a significant amount of **7** was produced. Several bases and phase transfer catalysts (PTC) were then screened to improve the selectivity (entries 5–9), and Cs₂CO₃ and Et₄NHCO₃ were the most effective for providing **4a** in 93% yield, with only a tiny amount of **6** (entry 9). We performed a control experiment using PPh₃ as a ligand instead of **5** (entry 10). The reaction unexpectedly proceeded with moderate yield, but a relatively large amount of phenyl(trimethyl)germane **8** was observed. This byproduct would be formed by reduction of **4a** or an aryl-aryl exchange between an arylpalladium intermediate and PPh₃ during the catalytic process.¹² We next investigated germylation of aryl triflate **2a** (entries 11–21). The optimized conditions for aryl bromide **1a** in entry 9 afforded no products, and **2a** remained intact (entry 11). The use of toluene as the sole solvent provided the desired product **3**, but the yield was low and a significant amount of **9** was observed

Figure 2 Scope and limitations of the germylation of aryl bromides **1** and aryl triflates **2**. **Conditions A:** **1** (1.0 equiv), **3** (1.2 equiv), Pd(OAc)₂ (10 mol %), **5** (20 mol %), Et₄NHCO₃ (10 mol %), and Cs₂CO₃ (1.2 equiv) in toluene/H₂O at 100 °C for 24 h. **Conditions B:** **1** or **2** (1.0 equiv), **3** (1.2 equiv), Pd(OAc)₂ (10 mol %), ligand **5** (20 mol %), Cs₂CO₃ (1.2 equiv), and Et₄NBr (1.0 equiv) in toluene at 120 °C for 24 h. Isolated yields are shown. See experimental section for detailed conditions and scale of each substrate. ^a 120 °C. ^b Only a trace amount of the desired product was observed in GC/MS analysis. ^c Pd(OAc)₂ (20 mol %) and **5** (40 mol %) were used. ^d KOAc instead of Cs₂CO₃ was used. ^e 130 °C. ^f **3** (2.0 equiv) was used. 62 h.

(entry 12). We speculated the lower reactivity of **2a** compared with **1a** might be due to the absence of a halide ion in the reaction, and several halide sources were screened as potential additives (entries 13–19). The addition of one equivalent of Et₄NBr was found to be effective, and the yield was improved to 49% (entry 19). Raising the reaction temperature to 120 °C further improved the yield (entry 20). Finally, the conditions without Et₄NHCO₃ resulted in a slightly better yield (entry 21), and were determined to be the optimal conditions for **2a**. Although a significant amount of **8** was observed at 120 °C, the yield of **4a** based on an internal standard was high (entries 20

and 21), indicating that **8** was derived from ligand **5** rather than **2a** or **4a** in these cases.

The scope and limitations of the optimized conditions for germylation are summarized in Figure 2. Both electron-deficient and electron-rich aryl bromides afforded the desired products in good yield (**4a**, **4b**). Various functional groups were well tolerated, providing germylated building blocks that are useful for further transformation (**4c–4f**). Heteroaryl bromides were reactive to give the corresponding germylated products (**4g**, **4h**, **4i**). The conditions optimized for aryl triflates (**Conditions B**) were more effective for less reactive aryl bromides to afford **4f**, **4h** and **4i**. 4-Bromophenol **1j**, however, failed to give the

germylated product **4j**, and phenol was detected as a major product under both reaction conditions. Germylated drug-like structures (**4k**,¹³ **4l**¹⁴) were accessible from the corresponding aryl bromides under *Conditions B*. In addition to aryl bromides, various types of aryl triflates afforded the desired germylated arenes. Electron-rich arenes such as **2n** and **2s** exhibited low reactivity (**4n**, **4s**), while highly electron-deficient substrates resulted in low yields due to fast hydrolysis of the sulfonate group (**4o**, **4p**). In some cases, the use of KOAc instead of Cs₂CO₃ was beneficial for avoiding the hydrolysis (**4o**, **4u**). Moderately electron-deficient aryl triflates were good substrates, and the products were obtained in good yield (**4a**, **4q**, **4r**, **4h**) under the standard conditions. The triflate of estrone **2t** exhibited low reactivity, but moderate yield was obtained using 20 mol % of Pd(OAc)₂ (**4t**).

We also investigated germylation of aryl iodide **10** under the optimized conditions for aryl bromides (Scheme 1). The conditions for aryl bromides were effective to provide **4a** in 95% yield at 80 °C, but the lower reaction temperature resulted in lower conversion.

Scheme 1 Germylation of aryl iodide **10**

When β -bromostyrene was used as a substrate, both *Conditions A* and *Conditions B* in Figure 2 afforded a dimerized product as a major product (see Supporting Information). Thus, the developed conditions were not suitable for germylation of alkenyl bromides.

The exact catalytic cycle was not elucidated, but a plausible cycle comprises oxidative addition of **1** or **2** to Pd(0), transmetalation with digermane **3**, and reductive elimination to release arylgermane **4**. The use of PPh₃ as a ligand also afforded the product in moderate yield (Table 1, entry 10), and therefore a hydroxy group of **5** would only have minor effects for the desired catalytic cycle, in contrast to the dramatic ligand effects observed in silylation.^{9g} The role of Et₄NBr in germylation of aryl triflates was unclear. A tetraethylammonium ion might be important rather than a bromide ion (Table 1, entries 13–19).

In summary, we developed general conditions for the germylation of aryl bromides **1** and aryl triflates **2** using hexamethyldigermane **3** under palladium catalysis. Various functionalized substrates, including drug-like molecules, afforded the germylated products in moderate to good yield, demonstrating the versatility of the presented protocols. These methods enable easy access to functionalized arylgermanes, and may encourage further investigation of the properties and reactivity of arylgermane derivatives.

Procedures

General: Reported melting points were uncorrected. Infrared (IR) spectra were recorded on a JASCO FT/IR-5300 spectrophotometer and

absorbance bands are reported in wave numbers (cm⁻¹). NMR spectra were recorded on JEOL JNM-ECS400 spectrometers operating at 391.78 MHz for ¹H NMR and 98.52 MHz for ¹³C NMR, JEOL JNM-ECX400 spectrometers operating at 395.88 MHz for ¹H NMR and 99.55 MHz for ¹³C NMR, and JNM-ECA500 spectrometers operating at 500.16 MHz for ¹H NMR and 125.77 MHz for ¹³C NMR. Chemical shifts were reported in the scale relative to TMS (0.00 ppm for ¹H NMR), CHCl₃ (7.26 ppm for ¹H NMR), CDCl₃ (77.0 ppm for ¹³C NMR), C₆HD₅ (7.15 ppm for ¹H NMR) and C₆D₆ (128.06 ppm for ¹³C NMR) as an internal reference, respectively. ESI mass spectra were measured on JEOL JMS-T100LCP spectrometer. Silica gel column chromatography was performed with Kanto Silica gel 60 N (40–50 mesh). Gel permeation chromatography was performed with YMC LC-forte/R using CHCl₃ as an eluent. Commercially available THF, toluene (Wako Ltd., deoxidized grade) were used without further manipulation unless otherwise stated. All aryl Triflates **2** were prepared from corresponding commercially available phenol. Aryl bromides **1a**, **1b**, **1c**, **1d**, **1h**, **1i** were commercially available and distilled under reduced pressure or recrystallized before use. 1-(4-Bromophenethyl)piperidine **1f**,¹⁵ 5-bromo-1-tosyl-1H-indole **1g**,¹⁶ 2-bromobenzo[b]thiophene **1i**,¹⁷ and ethyl 8-bromo-5-methyl-6-oxo-5,6-dihydro-4H-benzo[f]imidazo[1,5-a][1,4]diazepine-3-carboxylate **1k**¹⁴ were synthesized according to the literature. Structures of bromides **1** and aryl triflates **2** are listed in Figure S1 in Supporting Information. Hexamethyldigermane **3** was purchased from Sigma-Aldrich and used as received. All other reagents were commercially available and used as received.

General Procedure for Germylation of Aryl Bromides and Triflates

Conditions A: To a screw vial with a septum cap were added aryl bromide **1** (0.50 mmol), Pd(OAc)₂ (11.2 mg, 0.05 mmol, 10 mol %), ligand **5** (27.8 mg, 0.10 mmol, 20 mol %), Cs₂CO₃ (195.5 mg, 0.60 mmol, 1.2 equiv.), Et₄NHCO₃ (9.5 mg, 0.05 mmol, 10 mol %), hexamethyldigermane **3** (120 μ L, 0.60 mmol, 1.2 equiv.) and toluene (1.25 mL) under Ar atmosphere in a glove box. The vial was capped and removed from the glove box, and then H₂O (1.25 mL) was injected via syringe. The vial was heated at 100 °C for 24 h with stirring. After cooled to room temperature, the organic layer was separated, and the aqueous layer was extracted with EtOAc (3 mL $\times$ 3). The combined organic layers were washed with brine (3 mL), dried over Na₂SO₄. Filtration and evaporation gave a crude product, which was purified by silica gel column chromatography to give a corresponding product **4**.

Conditions B: To a dried screw capped vial were added aryl bromide **1** or aryl triflate **2** (0.50 mmol), Pd(OAc)₂ (11.2 mg, 0.05 mmol, 10 mol %), Ligand **5** (27.8 mg, 0.10 mmol, 20 mol %), Cs₂CO₃ (195.5 mg, 0.60 mmol, 1.2 equiv.), Et₄NBr (105.1 mg, 0.5 mmol, 1.0 equiv.), hexamethyldigermane **3** (120 μ L, 0.60 mmol, 1.2 equiv.) and toluene (2.5 mL) under Ar atmosphere in a glove box. The vial was capped and heated at 120 °C for 24 h with stirring. After cooled to room temperature, H₂O (2 mL) was added. After dilution with EtOAc, the organic layer was separated, and the aqueous layer was extracted with EtOAc (3 mL $\times$ 3). The combined organic layers were washed with brine (3 mL), and dried over Na₂SO₄. Filtration and evaporation gave a crude product, which was purified by silica gel column chromatography to give a corresponding product **4**.

(4-Chlorophenyl)trimethylgermane (4a)

Conditions A using 1-bromo-4-chlorobenzene **1a** (0.50 mmol) and purification of the crude product by silica gel column chromatography (hexane) followed by gel permeation chromatography afforded **4a** as a colorless oil (98.6 mg, 86% yield).

Conditions B using 4-chlorophenyl trifluoromethanesulfonate **2a** (0.50 mmol) and purification of the crude product by silica gel column chromatography (hexane) afforded **4a** as a colorless oil (95.1 mg, 83% yield).

Ethyl 2-(4-bromophenoxy)-2-methylpropanoate (1k)

4-Bromophenol (519 mg, 3.0 mmol) and Cs₂CO₃ (2.44 g, 7.5 mmol, 2.5 equiv) were dissolved in anhydrous DMF (10 mL). The solution was stirred for 10 min, and then ethyl-2-bromoisobutyrate (1.17 g, 6.0 mmol, 2.0 equiv) was added. The resulting reaction mixture was stirred at 100 °C for 23 h. After cooled to room temperature, the residue was taken up in EtOAc (50 mL). The solution was successively washed with H₂O (20 mL x 2) and brine (20 mL), and dried over Na₂SO₄. Filtration and evaporation gave a crude product, which was purified by silica gel column chromatography to give **1k** as a colorless oil (818 mg, 95% yield).

TLC: R_f = 0.50 (hexane/EtOAc = 5:1)
