Hokkaido University Collection of Scholarly and Academic Papers: HUSCAP
Thom form in equivariant Čech-de Rham theory

Ko Fujisawa

December 20, 2018

Abstract

In the present paper, we provide the foundation of a $G$-equivariant Čech-de Rham theory for a compact Lie group $G$ by using the Cartan model of equivariant differential forms. Our approach is quite elementary without referring to the Mathai-Quillen framework. In particular, by a direct computation, we give an explicit formula of the $U(l)$-equivariant Thom form of $\mathbb{C}^l$, which deforms the classical Bochnor-Martinelli kernel. Also we discuss a version of equivariant Riemann-Roch formula.

1 Introduction

As well known, the Čech-de Rham cohomology of a smooth manifold is a hypercohomology joining the Čech complex and the de Rham complex, which has been introduced for proving the equivalence between these two cohomology theories (cf. Bott-Tu [?]). Afterwards, Tatsuo Suwa has successfully established the Čech-de Rham theory as a tool for computing and describing explicit formulas at the level of cocycles; indeed, it yields several applications such as localization formulae of characteristic classes and index theorems of vector fields on possibly singular varieties (Suwa [?], [?], Brasselet-Seade-Suwa [?]) and also index theorems for fixed points of holomorphic self-maps (Abate-Bracci-Toven [?], Bracci-Suwa [?]). In the present paper, we provide the foundation of a $G$-equivariant version of the Čech-de Rham theory for a compact Lie group $G$ by combining Suwa’s construction with the classical Cartan model of equivariant differential forms.

Of our particular interest is to describe the equivariant characteristic classes and their localization at the level of cocycles in an explicit and constructible way. Let $M$ be a $G$-manifold and $\pi : E \to M$ a $G$-equivariant complex vector bundle of rank $l$ with the zero section $\Sigma \simeq M$. Put $\mathcal{W} = \{W_0, W_1\}$ with $W_0 = E \setminus \Sigma$ and $W_1 = E$. The equivariant Thom form is simply given as an element of the relative equivariant Čech-de Rham complex

$$(0, \pi^*\varepsilon_{eq}, -\psi_{eq}) \in \Omega^l_G(\mathcal{W}, W_0),$$

where $\varepsilon_{eq}$ is the equivariant Euler form and $\psi_{eq}$ is the equivariant angular form such that $d_{eq}\psi_{eq} = -\pi^*\varepsilon_{eq}$ (Theorem ??). A main result is an explicit expression of the universal
equivariant Thom form for the trivial $U(l)$-equivariant bundle $\mathbb{C}^l \to \{0\}$, that involves an $u(l)^*$-valued differential form whose constant term is just the classical Bochner-Martinelli kernel (Theorem ??). The equivariant Thom form of $E$ is now obtained from this universal form via the equivariant Chern-Weil map. In our approach, it may be constructed via the localization of equivariant characteristic classes. Indeed, the equivariant Thom class $\psi^E_{eq}$ is equal to the localized equivariant top Chern class with respect to the diagonal section $s_{\Delta}$:

$$\psi^E_{eq} = \psi^1_{X}(\pi^*E, s_{\Delta})_{eq}$$

(Theorem ??). Finally, we establish an essential version of equivariant Riemann-Roch theorem (Theorem ??):

$$\text{ch}^1_X(\lambda_{\pi^*E^*}, s_{\Delta})_{eq} = \psi^E_{eq} \cdot \text{td}^{-1}(\pi^*E)_{eq}.$$ 

The most emphasized point is as follows. In the theory of Mathai-Quillen [?], the equivariant Thom form is introduced through the fermionic integral and supersymmetry arguments, and in this context, Paradan-Vergne [?] described equivariant Thom forms for oriented real vector bundles in several variants of de Rham complex. In contrast, our approach is quite elementary and simply minded – basically we use only definite integrals for computations, without using the Mathai-Quillen framework. The present paper is the basis for further researches; for instance, it is promising to study $\bar{\partial}$-Thom forms and Atiyah classes in equivariant Čech-Dolbeault theory in complex holomorphic context; also another equivariant Čech-de Rham theory can be considered using the Borel construction via the simplicial method, instead of using the Cartan model as above, that certainly leads to the de Rham theory for differentiable stacks. Those will be discussed in somewhere else.

The present paper is organized as follows. In Section 1, after reviewing briefly the Cartan model, we describe the equivariant Čech-de Rham complex by following Suwa’s construction. In Section 2, we then take up the equivariant Chern-Weil theory in our setting. In particular, we show that our localized equivariant top Chern form provides an explicit formula of the universal $U(l)$-equivariant Thom form. Finally, in Section 3, we see that our equivariant Thom form immediately leads an equivariant version of the Riemann-Roch theorem for the zero locus of a section of a complex vector bundle.

The author would like to thank his supervisor, Toru Ohmoto, for guiding him to this subject and many instructions, and is also grateful to Tatsuo Suwa for his interests and his warm encouragement.

### 2 Equivariant Čech-de Rham cohomology

#### 2.1 Equivariant de Rham cohomology

Let $M$ be a smooth manifold and $G$ a Lie group with Lie algebra $\mathfrak{g}$. We denote by $(\Omega^*(M), d)$ the $\mathbb{C}$-valued de Rham complex of $M$ and by $\mathbb{C}[\mathfrak{g}]$ the algebra of polynomials
on \( \mathfrak{g} \) (which is isomorphic to the symmetric algebra \( S(\mathfrak{g}^*) \) of \( \mathfrak{g}^* \)). Suppose that \( G \) acts on \( M \) smoothly. Then, for each element \( X \in \mathfrak{g} \), we obtain a vector field denoted by \( X_M \):

\[
X_M(m) = \frac{d}{dt} \bigg|_{t=0} \exp(-tX) \cdot m
\]

And, for \( X \in \mathfrak{g} \), we denote by \( \iota_X \) the contraction with respect to \( X_M \):

\[
\iota_X := \iota(X_M) : \Omega^k(M) \to \Omega^{k-1}(M)
\]

If \( X_1, \ldots, X_n \) is a basis of \( \mathfrak{g} \), we will let \( x^1, \ldots, x^n \) denote the corresponding dual basis. Then we naturally get the left action of \( G \) on \( \Omega^*(M) \) and \( \mathbb{C}[\mathfrak{g}] \) as follows: For \( g \in G \),

\[
\omega \mapsto g \cdot \omega := L_{g^{-1}}^* \omega, \quad \omega \in \Omega^*(M)
\]

\[
x^I \mapsto g \cdot x^I := (\text{Ad}_g^* x)^I, \quad x^I \in \mathbb{C}[\mathfrak{g}]
\]

where \( L_{g^{-1}}^* \) is the pull back of a left transformation \( L_{g^{-1}} \) and \( \text{Ad}_g^* \) is the coadjoint action of \( G \) on \( \mathfrak{g}^* \) and \( I = (i_1, \ldots, i_n) \) is a multi-index.

**Definition 2.1.** \( \alpha = \sum_I x^I \otimes \omega_I \in \mathbb{C}[\mathfrak{g}] \otimes \Omega^*(M) \) is called \( G \)-equivariant differential form, if it satisfies the following condition: For any \( g \in G \)

\[
g \cdot \alpha := \sum_I g \cdot x^I \otimes g \cdot \omega_I = \sum_I x^I \otimes \omega_I = \alpha
\]

The wedge product of two equivariant forms is defined as the usual wedge product of differential forms. We denoted by \( \Omega^*_G(M) := (\mathbb{C}[\mathfrak{g}] \otimes \Omega^*(M))^G \) the algebra of \( G \)-equivariant differential forms. The degree of an equivariant form \( \alpha = x^I \otimes \omega_I \ (|I| = p, \omega_I \in \Omega^k(M)) \) is defined by \( \deg(\alpha) := 2p + k \). The wedge product of two equivariant forms is defined as follows; for \( X \in \mathfrak{g} \),

\[
(\alpha \wedge \beta)(X) := \alpha(X) \wedge \beta(X),
\]

where the wedge product on the right hand side is the usual wedge product of differential forms.

**Remark.** In other words, a \( G \)-equivariant differential form \( \alpha = \sum_I x^I \otimes \omega_I \) may be also regarded as a \( G \)-equivariant polynomial map \( \alpha : \mathfrak{g} \mapsto \Omega^*(M) \), i.e.

\[
\begin{align*}
\alpha(\sum \xi^i X_i) &= \sum \xi^i \omega_I, \quad \alpha(\text{Ad}_g X) = L_{g^{-1}}^* \alpha = g \cdot \alpha(X) \\
\mathfrak{g} \xrightarrow{\alpha} &\Omega^*(M) \\
\xrightarrow{\text{Ad}_g} &\Omega^*(M)
\end{align*}
\]
Definition 2.2. The twisted de Rham differential $d_{eq}$ is defined as follows. For $\alpha \in \Omega^*_G(M)$ and $X \in \mathfrak{g}$,

$$(d_{eq}\alpha)(X) := d(\alpha(X)) - \iota_X \alpha(X)$$

Then, it is easy to see $d_{eq} \circ d_{eq} = 0$ and $(\Omega^*_G(M), d_{eq})$ is a cochain complex (cf.[?]).

Definition 2.3. The $p$-th equivariant de Rham cohomology algebra is defined by the $p$-th cohomology of the $\mathbb{Z}$-graded complex $(\Omega^*_G(M), d_{eq})$:

$$H^p_G(M) := \text{Ker} d_{eq}^p / \text{Im} d_{eq}^{p-1}$$

Remark. If a compact Lie group $G$ acts on $M$ freely, we have the following isomorphism:

$$H^*_G(M) \cong H^*(M/G)$$

where $H^*(M/G)$ is the de Rham cohomology of $M/G$. (cf.[?])

Proposition 2.4. Let $M, N$ be $G$-manifolds. If $f : M \to N$ is $G$-morphism, then it induces a pull-back

$$f^* : \Omega^*_G(N) \to \Omega^*_G(M), \quad x^I \otimes \omega_I \mapsto x^I \otimes f^* \omega_I$$

and it satisfies that $d_{eq} f^* = f^* d_{eq}$. Therefore, we get a homomorphism

$$f^* : H^*_G(N) \to H^*_G(M)$$

2.2 Equivariant Čech-de Rham cohomology

Let $G$ be a compact Lie group and $M$ a $G$-manifold (i.e. a manifold given $G$-action). Let $\mathcal{U} = \{U_\alpha\}_{\alpha \in I}$ be a $G$-invariant open covering of $M$ (i.e. for any $g \in G$, $g \cdot U_\alpha = U_\alpha$). We assume that $I$ is an ordered set such that if $U_{\alpha_0 \cdots \alpha_r} := U_{\alpha_0} \cap \cdots \cap U_{\alpha_r} \neq \emptyset$, the induced order on the subset $\{(\alpha_0, ..., \alpha_r) \}$. We set

$$I^{(r)} = \{(\alpha_0, ..., \alpha_r) \in I^{r+1} | \alpha_0 < \cdots < \alpha_r, \ \alpha_\nu \in I\}.$$

Definition 2.5. We define $C^p(\mathcal{U}, \Omega^*_G)$ to be the direct product:

$$C^p(\mathcal{U}, \Omega^*_G) := \prod_{(\alpha_0, ..., \alpha_p) \in I^{(p)}} \Omega^*_G(U_{\alpha_0 \cdots \alpha_p}).$$

An element $\sigma \in C^p(\mathcal{U}, \Omega^*_G)$ assigns to each $(\alpha_0, ..., \alpha_p) \in I^{(p)}$ a form $\sigma_{\alpha_0 \cdots \alpha_p} \in \Omega^*_G(U_{\alpha_0 \cdots \alpha_p})$. The coboundary operator

$$\delta : C^p(\mathcal{U}, \Omega^*_G) \to C^{p+1}(\mathcal{U}, \Omega^*_G)$$

is defined by

$$(\delta \sigma)_{\alpha_0 \cdots \alpha_{p+1}} := \sum_{\nu=0}^{p+1} (-1)^{\nu} \sigma_{\alpha_0 \cdots \alpha_\nu \cdots \alpha_{p+1}},$$

where $\alpha_{p+1}$ is the $(p+1)$-th term in the ordered set $I^{(p+1)}$. Then, it is easy to see $\delta \circ \delta = 0$ and $(C^*(\mathcal{U}, \Omega^*_G), \delta)$ is a cochain complex (cf.[?]).
The natural homomorphism makes $C^*(\mathcal{U}, \Omega^r_G)$ a double complex. Put
\[
\Omega^r_G(\mathcal{U}) := \bigoplus_{p+q=r} C^p(\mathcal{U}, \Omega^q_G)
\]
and define for $p$-forms $\sigma \in C^p(\mathcal{U}, \Omega^q_G)$
\[
D_{eq}\sigma := \delta\sigma + (-1)^p d_{eq}\sigma.
\]

We call $(\Omega^r_G(\mathcal{U}), D_{eq})$ the equivariant Čech-de Rham complex and its $r$-th cohomology $H^r_G(\mathcal{U})$ the $r$-th equivariant Čech-de Rham cohomology of $\mathcal{U}$.

**Theorem 2.6.** The natural homomorphism $r : \Omega^r_G(\mathcal{M}) \to C^0(\mathcal{U}, \Omega^r_G) \subset \Omega^r_G(\mathcal{U})$ (which assigns to an $\omega \in \Omega^r_G(M)$ the cochain $\xi$ given by $\xi_\alpha = \omega|_{U_\alpha}$) induces an isomorphism:
\[
r : H^r_G(\mathcal{M}) \xrightarrow{\sim} H^r_G(\mathcal{U})
\]

**Proof.** The same argument as for non equivariant case (Suwa [?]) works. Here we use a $G$-equivariant partition of unity subordinate to the covering $\mathcal{U}$ (cf. Guillemin-Sternberg [?]).

The cup product of equivariant differential forms is also defined in the same way as in Suwa [?]. In particular, it holds that
\[
D_{eq}(\xi \cup \eta) = D_{eq}\xi \cup \eta + (-1)^r\xi \cup D_{eq}\eta.
\]

**Example 2.7.** (relative equivariant Čech-de Rham cohomology) Let $\mathcal{U} = \{U_0, U_1\}$ be a $G$-invariant open covering of $\mathcal{M}$. Then we have
\[
\Omega^r_G(\mathcal{U}) = \Omega^r_G(U_0) \oplus \Omega^r_G(U_1) \oplus \Omega^{r-1}_G(U_{01}).
\]
The differential of an element $\xi = (\xi_0, \xi_1, \xi_{01}) \in \Omega^r_G(\mathcal{U})$ is given by
\[
D_{eq}\xi = (d_{eq}\xi_0, d_{eq}\xi_1, \xi_1 - \xi_0 - d_{eq}\xi_{01}).
\]

Now we set
\[
\Omega^p_G(\mathcal{U}, U_0) = \{\xi = (\xi_0, \xi_1, \xi_{01}) \in \Omega^p_G(\mathcal{U}) | \xi_0 = 0\},
\]
which is a subcomplex of $(\Omega^r_G(\mathcal{U}), D_{eq})$. Then its $p$-th cohomology is called the $p$-th relative equivariant Čech-de Rham cohomology of $(\mathcal{U}, U_0)$ and we denote it by $H^p_G(\mathcal{U}, U_0)$.

In this case, the cup product $\Omega^r_G(\mathcal{U}) \times \Omega^{r'}_G(\mathcal{U}) \to \Omega^{r+r'}_G(\mathcal{U})$ is defined by
\[
(\xi_0, \xi_1, \xi_{01}) \cup (\eta_0, \eta_1, \eta_{01}) = (\xi_0 \wedge \eta_0, \xi_1 \wedge \eta_1, (-1)^r\xi_0 \wedge \eta_{01} + \xi_{01} \wedge \eta_1).
\]
Putting $\xi_0 = 0$, we have a paring $\Omega^r_G(\mathcal{U}, U_0) \times \Omega^{r'}_G(U_1) \to \Omega^{r+r'}_G(\mathcal{U}, U_0)$
\[
(0, \xi_1, \xi_{01}) \cup \eta_1 = (0, \xi_1 \wedge \eta_1, \xi_{01} \wedge \eta_1).
\]
2.3 Equivariant fiber integration and Thom form

We follow the same argument as in Suwa [?]. Hereafter, let $G$ be a compact Lie group.

**Definition 2.8.** $\pi : T \to M$ is called an **equivariant fiber bundle**, if $\pi : T \to M$ is a fiber bundle and $G$ acts on $T$ by bundle maps (in other words, $T, M$ are $G$-manifolds and $\pi : T \to M$ is $G$-morphism)

**Definition 2.9.** Let $M$ be an oriented compact manifold and $\pi : T \to M$ be an equivariant oriented fiber bundle with fiber $F$ of dimension $l$, where $F$ is compact oriented possibly with boundary. We define the $G$-equivariant fiber integration $\pi_*$ as follows;

$$(\pi_*(\alpha))(X) := \pi_*(\alpha(X)), \text{ for } \alpha \in \Omega^p_G(T), X \in \mathfrak{g},$$

where $\pi_*$ on the right hand side is the usual fiber integration (Refer to [?])

If $G$ acts on $T$ and $M$ preserving the orientations, directly computing, we see that $\pi_*(\Omega^p_G(T)) \subset \Omega^{p-1}_G(M)$. Namely, we get a $\mathbb{C}$-linear map

$$\pi_* : \Omega^p_G(T) \to \Omega^{p-1}_G(M)$$

**Proposition 2.10.** In the above situation, the equivariant fiber integration has the following fundamental properties:

(1) For $\alpha \in \Omega^p_G(T)$ and $\beta \in \Omega^q_G(M)$,

$$\pi_*(\alpha \wedge \pi^*\beta) = \pi_*(\alpha) \wedge \beta$$

(2) Let $\partial T$ be a boundary of $T$ and $i : \partial T \hookrightarrow T$ be the inclusion. Then we have

$$\pi_* \circ d_{eq} + (-1)^{l+1} d_{eq} \circ \pi_* = (\partial \pi)_* \circ i^*$$

**Proof.** It is shown in entirely the same way as the non equivariant case [?][?]. □

In the following, we introduce the $G$-equivariant fiber integration on relative equivariant Čech-de Rham cochains. Let $\pi : E \to M$ be a $G$-equivariant oriented vector bundle of rank $l$ (that is, $\pi : E \to M$ is a vector bundle and $G$ acts on $E$ by vector bundle maps). We identify $M$ with the image of the zero section of $E$. Setting $W_0 = E \setminus M$ and $W_1 = E$, $\mathcal{W} = \{W_0, W_1\}$ is a $G$-invariant open covering of $E$. Let $T_1 \to M$ be a closed unit ball bundle in $W_1$ with respect to some $G$-invariant Riemannian metric on $E$ (since $G$ is a compact Lie group, it exists) and set $T_0 = E \setminus \text{Int}T_1$. Then $\{T_0, T_1\}$ is honeycomb system adapted to $\mathcal{W}$ (for details, see [?]). Let $\pi_1$ and $\pi_{01}$ denote the restriction of $\pi$ to $T_1$ and $T_{01}$ respectively. Thus,

- $\pi_1 : T_1 \to M$ is a $G$-equivariant closed $l$-unit ball bundle
- $\pi_{01} : T_{01} \to M$ is a $G$-equivariant $(l-1)$-sphere bundle.
By the definition of honeycomb system, the orientation of $T_{01}$ is opposite to that of the boundary $\partial T_1$ of $T_1$.

**Definition 2.11.** The $G$-equivariant fiber integration on relative equivariant Čech-de Rham cochains

$$\pi_*: \Omega^p_G(W, W_0) \to \Omega_{G}^{p-l}(M)$$

is defined by

$$\pi_*\alpha := (\pi_1)_*\alpha_1 + (\pi_{01})_*\alpha_{01},$$

where $\alpha = (0, \alpha_1, \alpha_{01}) \in \Omega^p_G(W, W_0)$.

**Proposition 2.12.** For $\alpha \in \Omega^p_G(W, W_0)$, $\beta \in \Omega^q_G(W_1)$, we have

$$\pi_* (\alpha \lrcorner \pi^* \beta) = \pi_* \alpha \wedge \beta$$

**Proof.** Take $\alpha = (0, \alpha_1, \alpha_{01}) \in \Omega^p_G(W, W_0)$. By using Proposition ??,

$$\begin{align*}
\pi_* (\alpha \lrcorner \pi^* \beta) &= \pi_* (0, \alpha_1 \wedge \pi^* \beta, \alpha_{01} \wedge \pi^* \beta) \\
&= (\pi_1)_* (\alpha_1 \wedge \pi^* \beta) + (\pi_{01})_* (\alpha_{01} \wedge \pi^* \beta) \\
&= (\pi_1)_* \alpha_1 \wedge \beta + (\pi_{01})_* \alpha_{01} \wedge \beta \\
&= \pi_* \alpha \wedge \beta
\end{align*}$$

**Proposition 2.13.** In the above situation, we have the following formula;

$$\pi_* \circ D_{eq} + (-1)^{l+1} d_{eq} \circ \pi_* = 0$$

Thus $\pi_* : \Omega^p_G(W, W_0) \to \Omega_{G}^{p-l}(M)$ induces a homomorphism $\pi_* : H^p_G(W, W_0) \to H^p_{G}^{p-l}(M)$.

**Proof.** Applying Proposition ?? to $\pi_1, \pi_{01}$ and noting that $(\partial \pi_1)_* = -(\pi_0)_*$, we obtain the above formula by directly computing.

The same Mayer-Vietoris argument in non-equivariant case (Theorem 5.3 in [?]) shows that $\pi_* : H^p_G(W, W_0) \to H^p_{G}^{p-l}(M)$ is isomorphism. Then, there exists the inverse map

$$(\pi_*)^{-1} : H^p_{G}^{p-l}(M) \xrightarrow{\sim} H^p_G(W, W_0)$$

and we denote it by $T_E$ and call it the $G$-equivariant Thom isomorphism. Then, setting

$$\Psi_{eq}^E := T_E([1]) \in H^1_G(W, W_0) \quad (1 \in \Omega^0_G(M)),$$

we call it $G$-equivariant Thom class. It follows from Proposition ?? that

$$\pi_* T_E([1]) \lrcorner \pi^* \beta = \pi_* T_E([1]) \wedge \beta = \beta$$

$$\implies T_E(\beta) = \Psi_{eq}^E \lrcorner \pi^* \beta$$

Then, we may take the following form as representative element of $\Psi_{eq}^E$. 

7
Theorem 2.14. The equivariant Thom class $\Psi_{eq}^E \in H^l_G(\mathcal{W}, W_0)$ is represented by the following form

$$(0, \pi^*\varepsilon_{eq}, -\psi_{eq}) \in \Omega^l_G(\mathcal{W}, W_0),$$

where $\varepsilon_{eq}$ is $d_{eq}$-closed $G$-equivariant $l$-form on $M$ and $\psi_{eq}$ is $G$-equivariant $(l - 1)$-form on $W_0$ such that

$$d_{eq}\psi_{eq} = -\pi^*\varepsilon_{eq} \text{ in } W_0 \text{ and } - (\pi_{01})_*\psi_{eq} = 1.$$

Proof. Suppose that $\Psi_{eq}^E = [(0, \psi_1, \psi_{01})] \in H^l_G(\mathcal{W}, W_0)$. Since

$$D_{eq}(0, \psi_1, \psi_{01}) = (0, d_{eq}\psi_1, \psi_1 - d_{eq}\psi_{01}) = 0,$$

we see that $\psi_1$ is closed $l$-form on $W_1$ and $\psi_{01}$ is $(l - 1)$-form such that $d_{eq}\psi_{01} = \psi_1$ on $W_0$. Note that $\pi : E = W_1 \to M$ induces an isomorphism equivariant de Rham cohomology, because $\pi$ is $G$-equivariant deformation retract. So there exists $\phi_1 \in \Omega^{l-1}_G(W_1)$ and $\varepsilon_{eq} \in \Omega^l_G(M)$ such that

$$\psi_1 = \psi^*\varepsilon_{eq} + d_{eq}\phi_1.$$

Here, setting $\psi_{eq} := -\psi_{01} + \phi_1$ which is $(l - 1)$-form on $W_0$, we see that

$$(0, \psi_1, \psi_{01}) = (0, \pi^*\varepsilon_{eq}, -\psi_{eq}) + D_{eq}(0, \phi_1, 0).$$

Thus, $\psi_E$ is represented by $(0, \pi^*\varepsilon_{eq}, -\psi_{eq})$. Then we have

$$d_{eq}\psi_{eq} = -d_{eq}\psi_{01} + d\phi_1 = -\psi_1 + (\psi_1 - \pi^*\varepsilon_{eq}) = -\pi^*\varepsilon.$$

Moreover, we have

$$(\pi_1)_*\psi_1 = (\pi_1)_*\pi^*\varepsilon_{eq} + (\pi_{01})_*d_{eq}\phi_1$$

$$= (\pi_1)_*d_{eq}\phi_1 = (\partial\pi_1)_*\phi_1 + (-1)^l d_{eq}(\pi_1)_*\phi_1$$

$$= - (\pi_{01})_*\phi_1.$$

From this and $\pi_*(0, \psi_1, \psi_{01}) = 1$, it follow that

$$(\pi_1)_*\psi_1 + (\pi_{01})_*\psi_{01} = 1 \iff (\pi_1)_*\psi_1 + (\pi_{01})_*\phi_1 - (\pi_{01})_*\psi_{eq} = 1$$

$$\iff - (\pi_{01})_*\psi_{eq} = 1.$$

Remark. The form $\varepsilon_{eq}$ above is called a $G$-equivariant Euler form and $\psi_{eq}$ is called a $G$-equivariant global angular form.
3 Equivariant Chern-Weil theory and Localization

3.1 Equivariant Chern-Weil theory

Let $G$ be a compact Lie group and $\pi : E \to M$ a complex $G$-equivariant vector bundle of rank $l$. We denote by $\Omega^*(M, E)$ the set of $E$-valued differential forms on $M$. Then we define the set of $E$-valued $G$-equivariant differential forms on $M$ by

$$\Omega^*_G(M, E) := (\mathbb{C}[g] \otimes \Omega^*(M, E))^G,$$

where $G$ acts on the section of $E$ such that for $g \in G$ and $s \in \Omega^0(M, E)$

$$(g \cdot s)(m) := g \cdot s(g^{-1} \cdot m).$$

Note that $\Omega^*_G(M, E)$ is the $\Omega^0_G(M)$-module.

**Definition 3.1.**

1. A connection $\nabla : \Omega^*(M, E) \to \Omega^{*+1}(M, E)$ is called a $G$-invariant connection, if $\nabla$ commutes with $G$-action on $\Omega^*(M, E)$, that is, $g\nabla = \nabla g$;

$$\begin{array}{ccc}
\Omega^*(M, E) & \xrightarrow{\nabla} & \Omega^{*+1}(M, E) \\
g & \downarrow & g \\
\Omega^*(M, E) & \xrightarrow{\nabla} & \Omega^{*+1}(M, E).
\end{array}$$

2. The *equivariant connection* $\nabla_{eq}$ corresponding to a $G$-invariant connection $\nabla$ is the operator on $\mathbb{C}[g] \otimes \Omega^*(M, E)$ defined by the formula: for $X \in \mathfrak{g}$, $\alpha \in \mathbb{C}[g] \otimes \Omega^*(M, E)$,

$$(\nabla_{eq} \alpha)(X) := (\nabla - \iota_X)\alpha(X).$$

**Lemma 3.2.** If $\alpha \in \Omega^*_G(M, E)$, then $\nabla_{eq} \alpha \in \Omega^{*+1}_G(M, E)$.

**Proof.** Using $\alpha(\text{Ad}_g X) = g \cdot \alpha(X)$, $g\nabla = \nabla g$ and $\iota_{\text{Ad}_g X} = g \cdot \iota_X \cdot g^{-1}$, we easily see that $(\nabla_{eq} \alpha)(\text{Ad}_g X) = g \cdot (\nabla_{eq} \alpha)(X)$. \qed

**Definition 3.3.** The equivariant curvature $K_{eq} : \Omega^0_G(M, E) \to \Omega^2_G(M, E)$ of an equivariant connection $\nabla_{eq}$ is defined by the formula:

$$K_{eq}(X) := \nabla_{eq}(X)^2 + L_X^E,$$

where $L_X^E$ is an infinitesimal action of $\mathfrak{g}$ induced by the $G$-action on $\Omega^0_G(M, E)$.

**Lemma 3.4.** For $f \in \Omega^0_G(M)$ and $s \in \Omega^0_G(M, E)$, we have

$$K_{eq}(fs) = fK_{eq}(s).$$

Thus $K_{eq}$ is an element of $\Omega^2_G(M, \text{End}(E))$. 9
In the following, we define $G$-equivariant characteristic classes. Let $\nabla$ be a $G$-invariant connection, $\nabla_{eq}$ its equivariant connection and $K_{eq}$ its equivariant curvature as above. Take a $G$-invariant open set $U$ in $M$ such that $E$ is trivial on $U$. If $s^{(l)} = (s_1, ..., s_l)$ is a local frame of $E$ on $U$, we may write, for $i = 1, ..., l$ and $X \in \mathfrak{g}$

\[
(\nabla_{eq}s_i)(X) = \sum_{j=1}^{l} \theta_{ji} \otimes s_j, \quad \theta_{ij} \in \Omega^1(U),
\]

\[
(K_{eq}s_i)(X) = \sum_{j=1}^{l} \kappa_{ji}(X) \otimes s_j, \quad \kappa_{ij} \in (\mathbb{C}[\mathfrak{g}] \otimes \Omega^0(U)) \oplus \Omega^2(U).
\]

We call $\theta = (\theta_{ij})$ the connection matrix and $\kappa = (\kappa_{ij})$ the equivariant curvature matrix with respect to $s^{(l)}$. From the definition, $\kappa_{ij}$ is computed explicitly as follows. Letting $L^E_X s_i = \sum_{j=1}^{l} \ell_{ji}(X)s_j$, we have

\[
(K_{eq}s_i)(X) = \nabla^2 s_i - \iota_X \nabla s_i + L^E_X s_i
\]

\[
= \sum_{j=1}^{l} \{d\theta_{ji} + \sum_{k=1}^{l} \theta_{jk} \wedge \theta_{ki} - \iota_X \theta_{ij} + \ell_{ji}(X)\} \otimes s_j
\]

and thus

\[
\kappa_{ij}(X) = d\theta_{ij} + \sum_{k=1}^{l} \theta_{ik} \wedge \theta_{kj} - \iota_X \theta_{ij} + \ell_{ji}(X).
\]

We will use this equality in the proof of Theorem ?? later. Moreover, this leads to an equivariant version of well-known Bianchi identity. For completeness, we prove it:

**Lemma 3.5** (equivariant Bianchi identity). It holds that $d_{eq}\kappa = [\kappa, \theta]$.

**Proof.** Noting that $L^E_X s_i = \nabla L^E_X s_i$ (since $\nabla$ is $G$-invariant) and comparing the both sides locally, we have

\[-L_X \theta_{ji} + d\ell(X)_{ji} = \sum_{k=1}^{l} (\ell_{jk}(X)\theta_{ki} - \theta_{ik}\ell_{kj}(X))
\]

Thus,

\[
d_{eq}\kappa_{ij}(X) = d\kappa_{ij}(X) - \iota_X \kappa_{ij}(X)
\]

\[
= \sum_{k=1}^{l} (d\theta_{ik} \wedge \theta_{kj} - \theta_{ik} \wedge d\theta_{kj}) - \sum_{k=1}^{l} (\iota_X (\theta_{ik})\theta_{kj} - \iota_X (\theta_{kj})\theta_{ik})
\]

\[-d\ell_{ij}(X) - \iota_X d\theta_{ij} + d\ell_{ji}(X)
\]

\[
= \sum_{k=1}^{l} \{d\theta_{ik} - \iota_X \theta_{ik} \wedge \theta_{kj} - \theta_{ik} \wedge (d\theta_{kj} - \iota_X \theta_{kj})\} - L_X \theta_{ij} + d\ell_{ji}(X)
\]

\[
= \sum_{k=1}^{l} \{(d_{eq}\theta_{ik} + \ell_{ik}(X)) \wedge \theta_{kj} - \theta_{ik} \wedge (d_{eq}\theta_{kj} + \ell_{kj}(X))\}
\]
Therefore, letting $\ell(X) = (\ell_{ij}(X))$, the above equation may be written in terms of a matrix form as

\[
d_{eq}\kappa = (d_{eq}\theta + \ell(X)) \wedge \theta - \theta \wedge (d_{eq}\theta + \ell(X)) = (d_{eq}\theta + \theta \wedge \ell(X)) \wedge \theta - \theta \wedge (d_{eq}\theta + \theta \wedge \ell(X)) = \kappa \wedge \theta - \theta \wedge \kappa = [\kappa, \theta].
\]

For a homogeneous invariant polynomial $\phi$ (that is, $\phi \in \mathbb{C}[\mathfrak{gl}(l, \mathbb{C})]^{GL(l, \mathbb{C})}$), the $G$-equivariant characteristic form is defined by

\[
\phi(\nabla_{eq}) := \phi(\kappa).
\]

Then, it follows from the equivariant Bianchi identity that $\phi(\nabla_{eq})$ is $d_{eq}$-closed and this is independent of the choice of a local frame of $E$ (Lemma ??). The $G$-equivariant characteristic class of $E$ for an invariant polynomial $\phi$ is defined by

\[
\phi(E)_{eq} := [\phi(\nabla_{eq})] \in H^*_G(M).
\]

In fact, this class is independent of the choice of $\nabla_{eq}$ (see below).

Now, we switch to the setting of equivariant Čech-de Rham cohomology. We need the following $G$-equivariant Bott-difference form:

**Proposition 3.6** (Bott’s difference form). Suppose $\nabla_{eq}^{(0)}, \ldots, \nabla_{eq}^{(p)}$ are $G$-equivariant connections for $E$. For a homogeneous invariant polynomial $\phi$ of degree $k$, there is a form $\phi(\nabla_{eq}^{(0)}, \ldots, \nabla_{eq}^{(p)}) \in \Omega^{2k-p}_G(M)$ satisfying the following properties:

1. $\phi(\nabla_{eq}^{(0)}, \ldots, \nabla_{eq}^{(p)})$ is alternating in the $p+1$ entries
2. $\sum_{\nu=0}^{p} (-1)^\nu \phi(\nabla_{eq}^{(0)}, \ldots, \nabla_{eq}^{(\nu)}, \nabla_{eq}^{(p)}) + (-1)^p d_{eq} \phi(\nabla_{eq}^{(0)}, \ldots, \nabla_{eq}^{(p)}) = 0$

We call $\phi(\nabla_{eq}^{(0)}, \ldots, \nabla_{eq}^{(p)})$ a $G$-equivariant Bott-difference form with respect to $G$-equivariant connections $\nabla_{eq}^{(0)}, \ldots, \nabla_{eq}^{(p)}$.

**Proof.** Let $\rho : \mathbb{R}^p \times M \to M$ be the natural projection, where $G$ acts on $\mathbb{R}^p$ trivially. Then, we define a $G$-equivariant connection $\tilde{\nabla}_{eq}$ for $\rho^*E$ by

\[
\tilde{\nabla}_{eq} = (1 - \sum_{\nu=1}^{p} \ell_{\nu}) \rho^*\nabla_{eq}^{(0)} + \sum_{\nu=1}^{p} \ell_{\nu} \rho^*\nabla_{eq}^{(\nu)}.
\]

Letting $\rho' : \Delta^p \times M \to M$ be the restriction of $\rho$, we get the fiber integration

\[
\rho'_* : \Omega^*_G(\Delta^p \times M) \to \Omega^{*+p}_G(M),
\]

where $\Delta^p$ is the standard $p$-simplex. And, setting

\[
\phi(\nabla_{eq}^{(0)}, \ldots, \nabla_{eq}^{(p)}) := \rho'_* \phi(\tilde{\nabla}),
\]

we have the desired form satisfying (1), (2) (Use the Stokes theorem and the formula Proposition ?? (2)).
Let \( U = \{ U_\alpha \}_{\alpha \in I} \) be a \( G \)-invariant open covering of \( M \) as in section 1.2. Let \( \pi : E \to M \) be a complex vector bundle of rank \( l \) and \( \phi \) an invariant polynomial homogeneous of degree \( k \). For each \( \alpha \), we choose a connection \( \nabla^{(\alpha)}_e \) for \( E|_{U_\alpha} \) and for the collection \( \nabla^*_e = (\nabla^{(\alpha)}_e)_{\alpha \in I} \), we define \( \phi(\nabla^*_e) \in \Omega^k_G(U) \) by

\[
\phi(\nabla^*_e)_{\alpha_0 \ldots \alpha_p} := \phi(\nabla^{(0)}_e, \ldots, \nabla^{(p)}_e) \in \Omega^{2k-p}_G(U_{\alpha_0 \ldots \alpha_p})
\]

**Lemma 3.7.** In the above situation, we have the followings.

1. \( D_{eq} \phi(\nabla^*_e) = 0 \)

2. For another collection \( \nabla^*_e = (\nabla^{(\alpha)}_e)_{\alpha \in I} \), there exists the element \( \psi \in \Omega^{2k-1}_G(U) \) such that

\[
\phi(\nabla^*_e) - \phi(\nabla^*_e) = D_{eq} \psi.
\]

**Proof.** (1) By direct computations. (2) Setting

\[
\psi = \sum_{\nu=0}^p \phi(\nabla^{(\alpha_0)}_e, \ldots, \nabla^{(\alpha_\nu)}_e, \nabla^{(\alpha_{\nu+1})}_e, \ldots, \nabla^{(\alpha_p)}_e),
\]

we easily see that \( \phi(\nabla^*_e) - \phi(\nabla^*_e) = D_{eq} \psi. \)

It follows from this lemma that the element \( \phi(\nabla^*_e) \) defines a cohomology class \( [\phi(\nabla^*_e)] \in H^{2k}_G(U) \) which depends only on \( E \) but not on the choice of the collection of connections \( \nabla^*_e \). Also, from the following theorem, we may naturally regard \( [\phi(\nabla^*_e)] \) as a characteristic class in \( H^*_G(U) \).

**Theorem 3.8.** The class \( [\phi(\nabla^*_e)] \) in \( H^*_G(U) \) corresponds to the class \( \phi(E)_{eq} \) in \( H^*_G(M) \) under the isomorphism of Theorem ??

**Proof.** Take an equivariant connection \( \nabla_{eq} \) on \( M \). For each \( U_\alpha \in U \), defining \( \nabla^{(\alpha)}_{eq} \) to be \( \nabla_{eq}|_{U_\alpha} \), we see that it is an equivariant connection for \( E|_{U_\alpha} \). Then for the collection \( \nabla^*_e = (\nabla^{(\alpha)}_{eq}_e)_{\alpha \in I} \), by definition,

\[
\phi(\nabla^*_e) \in C^0(U, \Omega^*_G).
\]

Thus, \( r(\phi(\nabla_{eq})) = \phi(\nabla^*_e) \) and \( r([\phi(\nabla^*_e)]) = \phi(E)_{eq}. \)

As usual, the total equivariant Chern form is given by

\[
c^*(\nabla_{eq}) := \det(I + \frac{1}{2\pi} \kappa) = 1 + c^1_{eq}(\nabla_{eq}) + \cdots + c^l_{eq}(\nabla_{eq}) \in \Omega^*_G(M)
\]

and the total equivariant Chern class of \( E \) is defined by its cohomology class

\[
c^*_eq(E) = 1 + c^1_{eq}(E) + \cdots + c^l_{eq}(E) \in H^*_G(M).
\]

Note that the form \( c^*(\nabla_{eq}) \) and the class \( c^*_eq(E) \) is invertible in \( \Omega^*_G(M) \) and \( H^*_G(M) \) respectively. In the same way as the non equivariant case, the equivariant Chern form (or class) has functoriality with respect to a pull-back and additivity with respect to an exact sequence.
3.2 Localized equivariant characteristic classes

Let $M$ be a $G$-manifold and $S$ a $G$-invariant closed set in $M$ and $\pi : E \to M$ a complex $G$-equivariant vector bundle of rank $l$. Letting $U_0 = M \setminus S$ and $U_1$ a $G$-invariant neighborhood of $S$, we consider the $G$-invariant covering $U = \{U_0, U_1\}$. In what follows, let $H_G(U, U_0)$ denote $H_G(M, M \setminus S)$.

Suppose there is some “geometric object” $\gamma$ on $U_0$, to which is associated a class $\mathcal{C}$ of equivariant connections for $E$ on $U_0$ such that, for a certain homogeneous invariant polynomial $\phi$,

$$\phi((\nabla^{(0)}_{eq}), \ldots, (\nabla^{(k)}_{eq})) \equiv 0 \quad \text{if every } (\nabla^{(i)}_{eq}) \text{ belongs } \mathcal{C}.$$ 

A equivariant connection $(\nabla_{eq})_0$ for $E$ on $U_0$ is said to be special, if $(\nabla_{eq})_0$ belongs to $\mathcal{C}$ and the polynomial $\phi$ as above is said to be adapted to $\gamma$.

**Lemma 3.9.** In the above situation, suppose that $\nabla^{0}_{eq}$ is special and $\phi$ is adapted to $\gamma$. The class of

$$\phi(\nabla_{eq}) = (0, \phi(\nabla^{0}_{eq}), \phi(\nabla^{0}_{eq}, \nabla^{1}_{eq})) \in \Omega^*_G(U, U_0)$$

is independent of the choice of the special equivariant connection $\nabla^{0}_{eq}$ or in the equivariant connection $\nabla^{1}_{eq}$.

**Proof.** If $\nabla^{0}_{eq}$ and $\nabla^{0}_{eq}$ are both special, by using $\phi(\nabla^{0}_{eq}, \nabla^{0}_{eq}) = 0$ and Proposition 3.2, we have

$$(0, \phi(\nabla^{0}_{eq}), \phi(\nabla^{0}_{eq}, \nabla^{1}_{eq})) - (0, \phi(\nabla^{0}_{eq}), \phi(\nabla^{0}_{eq}, \nabla^{1}_{eq})) = D_{eq}(0, 0, \phi(\nabla^{0}_{eq}, \nabla^{0}_{eq}, \nabla^{1}_{eq})).$$

Similarly, for equivariant connections $\nabla^{0}_{eq}$ and $\nabla^{1}_{eq}$ on $U_1$,

$$(0, \phi(\nabla^{0}_{eq}), \phi(\nabla^{0}_{eq}, \nabla^{1}_{eq})) - (0, \phi(\nabla^{0}_{eq}), \phi(\nabla^{0}_{eq}, \nabla^{1}_{eq})) = D_{eq}(0, 0, \phi(\nabla^{0}_{eq}, \nabla^{0}_{eq}, \nabla^{1}_{eq})).$$

From this, we may define the following.

**Definition 3.10.** If $(\nabla_{eq})_0$ is special and $\phi$ (homogeneous of degree $d$) is adapted to $\gamma$, the class $\phi_S(E, \gamma) \in H^2_d(M, M \setminus S)$ is defined by

$$\phi_S(E, \gamma) := [\phi(\nabla_{eq})]$$

and is called the localized equivariant characteristic class of $\phi(E)_{eq}$ at $S$ by $\gamma$.

In the following, we consider a geometric object by frames and its localized equivariant Chern class. Suppose $\pi : E \to M$ is a complex $G$-equivariant vector bundle of rank $l$. Then, it follows from a way of definition of the $G$-equivariant Bott-difference form that for any $k$ equivariant connections $\nabla^{(1)}_{eq}, \ldots, \nabla^{(k)}_{eq}$ for $E$,

$$c^i(\nabla^{(1)}_{eq}, \ldots, \nabla^{(k)}_{eq}) \equiv 0 \quad \text{for } i \geq l + 1$$

As a consequence, we have the following.
Lemma 3.11. Let \( s^{(r)} = (s_1, ..., s_r) \) be an \( r \)-frame of \( E \) on a \( G \)-invariant open set \( U \) in \( M \). If \( \nabla_{eq}^{(1)}, ..., \nabla_{eq}^{(k)} \) is \( s^{(r)} \)-trivial on \( U \), then on \( U \)

\[
c^i(\nabla_{eq}^{(1)}, ..., \nabla_{eq}^{(k)}) \equiv 0 \quad \text{for } i \geq l - r + 1.
\]

From this, we have the following.

Definition 3.12. Let \( s^{(r)} \) be a local frame on \( M \setminus S \). If \( \nabla_{eq}^0 \) is \( s^{(r)} \)-trivial, by Lemma 3.11,

\[
c^i(\nabla_{eq}^0) = (0, c^i(\nabla_{eq}^1), c^i(\nabla_{eq}^0, \nabla_{eq}^1)) \quad \text{for } i \geq l - r + 1
\]

and induce the class \( [c^i(\nabla_{eq}^0)] \in H_{\Gamma}^2(M, M \setminus S) \). Since this class is independent of the choice of \( s^{(r)} \)-trivial \( G \)-equivariant connection \( \nabla_{eq}^0 \) on \( U_0 \) and a \( G \)-equivariant connection \( \nabla_{eq}^1 \) on \( U_1 \) by Lemma 3.11, we denote by

\[
c^i_S(E, s^{(r)}): [c^i(\nabla_{eq}^*)]
\]

and we call it the localized Chern class of \( c^i(E)_{eq} \) by \( s^{(r)} \) at \( S \).

3.3 Equivariant Thom class via localized Chern class

Suppose the unitary group \( U(l) \) (\( u(l) \) is the Lie algebra of \( U(l) \)) acts on \( \mathbb{C}^l \) naturally. Then

\[
\pi : \mathbb{C}^l \to \{0\}
\]

is clearly an \( U(l) \)-equivariant vector bundle. Setting

\[
W_0 = \mathbb{C}^l \setminus \{0\}, \quad W_1 = \mathbb{C}^l,
\]

we have an \( U(l) \)-invariant covering \( W = \{W_0, W_1\} \). We consider the pull-back of \( \mathbb{C}^l \) by \( \pi \), i.e.,

\[
\pi^*\mathbb{C}^l = \{(z_1, z_2) \in \mathbb{C}^l \times \mathbb{C}^l | \pi(z_1) = \pi(z_2)\} = \mathbb{C}^l \times \mathbb{C}^l
\]

\[
\varpi : \pi^*\mathbb{C}^l = \mathbb{C}^l \times \mathbb{C}^l \to \mathbb{C}^l,
\]

where \( \varpi \) is the projection to the second factor. From the definition of pull-back, \( U(l) \) acts on \( \mathbb{C}^l \times \mathbb{C}^l \) diagonally (\( A(z_1, z_2) = (Az_1, Az_2) \)) and \( \varpi : \pi^*\mathbb{C}^l = \mathbb{C}^l \times \mathbb{C}^l \to \mathbb{C}^l \) is an \( U(l) \)-equivariant vector bundle. Then the diagonal section

\[
s_\Delta : \mathbb{C}^l \to \pi^*\mathbb{C}^l = \mathbb{C}^l \times \mathbb{C}^l, \quad z \mapsto (z,z)
\]

is naturally \( U(l) \)-invariant frame on \( \mathbb{C}^l \setminus \{0\} \). Thus, we may consider the localized Chern class of \( c^i(\pi^*\mathbb{C}^l)_{eq} \) by \( s_\Delta \), that is,

\[
c^i(\pi^*\mathbb{C}^l, s_\Delta)_{eq} \in H_{\Gamma}^2(U(l))(\mathbb{C}^l, \mathbb{C}^l \setminus \{0\})
\]

This class is represented by the following form

\[
(0, c^i_{eq}(D_{eq}^1), c^i_{eq}(D_{eq}^0, D_{eq}^1)) \in \Omega_{U(l)}^2(W, W_0),
\]

where
• $D^0_{eq}$ is an $s_\Delta$-trivial $U(l)-$equivariant connection for $\pi^*\mathbb{C}^l$ on $W_0 = \mathbb{C}^l \setminus \{0\}$,

• $D^1_{eq}$ is an $U(l)$-equivariant connection for $\pi^*\mathbb{C}^l$ on $W_1 = \mathbb{C}^l$.

On the other hand, as a real vector bundle of rank $2l$, we may consider the $U(l)$-equivariant Thom class $\psi^{\mathbb{C}^l}_{eq} \in H^2_{U(l)}(\mathbb{C}^l, \mathbb{C}^l \setminus \{0\})$.

**Theorem 3.13.** [equivariant universal Thom class] In the above situation, we have

$$c^l(\pi^*\mathbb{C}^l, s_\Delta)_{eq} = \psi^{\mathbb{C}^l}_{eq}.$$ 

**Proof.** Setting 

$$T_1 = D^{2l} = \{z \in \mathbb{C}^l \mid \|z\| \leq 1\}, \quad T_0 = \mathbb{C}^l \setminus \text{Int}T_1,$$

we have a honeycomb system $\{T_0, T_1\}$ adapted to $W$. Note that $T_{01} = -S^{2l-1}$. By the definition of $\psi^{\mathbb{C}^l}_{eq}$, it suffices to find the equivariant connections $D^0_{eq}, D^1_{eq}$ satisfying

$$(\pi_1)_* c^l(D^1_{eq}) + (\pi_{01})_* c^l(D^0_{eq}; D^1_{eq}) = 1,$$

where $\pi_1 : T_1 \to \{0\}$, $\pi_{01} : T_{01} \to \{0\}$. Let sections $s_1, \ldots, s_l$ of $\varpi : \pi^*\mathbb{C}^l \to \mathbb{C}^l$ be

$$s_i(z) = (e_i, z) \quad (i = 1, \ldots, l),$$

where $\{e_i\}$ is the standard basis of $\mathbb{C}^l$. Now we define the connection $D_1$ for $\pi^*\mathbb{C}^l$ on $\mathbb{C}^l$ by

$$D_1(\sum_{i=1}^l f_i s_i) := \sum_{i=1}^l d f_i \otimes s_i \quad \text{(for } f_i \in C^\infty(\mathbb{C}^l)), $$

which is $s^l = (s_1, \ldots, s_l)$-trivial. Also, we easily see that $D_1$ is a $U(l)$-invariant connection. Thus we may define the equivariant connection $D^1_{eq}$ corresponding to $D_1$. From the definition of $D^1_{eq}$, the form degree of its curvature form is 0 and $(\pi_1)_* c^l(D^1_{eq}) = 0$.

Next we define the connection $D_0$ for $\pi^*\mathbb{C}^l$ on $\mathbb{C}^l \setminus \{0\}$ by

$$D_0 s_i = -\bar{z}_i \sum_{j=1}^l \frac{d z_j \otimes s_j}{\|z\|^2} \quad (i = 1, \ldots, l)$$

For $f_i \in C^\infty(\mathbb{C}^l \setminus \{0\})(i = 1, \ldots, l)$, $g \in U(l)$, we have

$$g \cdot D_0(\sum_{i=1}^l f_i s_i) = \sum_{i=1}^l ((g \cdot d f_i) \otimes (g \cdot s_i) + (g \cdot f_i)(g \cdot D_0 s_i))$$

$$D_0(g \cdot (\sum_{i=1}^l f_i s_i)) = \sum_{i=1}^l ((g \cdot d f_i) \otimes (g \cdot s_i) + (g \cdot f_i)(D_0(g \cdot s_i))).$$
Therefore, to show that $D_0$ is $U(l)$-invariant connection, it suffices to check

$$g \cdot (D_0 s_i) = D_0 (g \cdot s_i).$$

For $g = (g_{ij}) \in U(l)$, directly computing, we have

$$g \cdot \left( -\frac{\bar{z}_k}{\|z\|^2} \right) = -\sum_{k=1}^l g_{ki} \frac{\bar{z}_k}{\|z\|^2}$$

Thus, we have

$$g \cdot (D_0 s_i) = -\sum_{k=1}^l g_{ki} \frac{\bar{z}_k}{\|z\|^2} \sum_{j=1}^l \left\{ \left( \sum_{m=1}^l \overline{g_{mj}} dz_m \right) \otimes \left( \sum_{n=1}^l g_{nj} s_n \right) \right\}$$

and

$$D_0(g \cdot s_i) = D_0 \left( \sum_{k=1}^l g_{ki} s_k \right) = \sum_{k=1}^l g_{ki} D_0 s_k = -\sum_{k=1}^l g_{ki} \frac{\bar{z}_k}{\|z\|^2} \sum_{j=1}^l dz_j \otimes s_j.$$
and denote $\rho^*D^0_{eq}, \rho^*D^1_{eq}$ by $D^0_{eq}, D^1_{eq}$ for short. Then the connection matrix $\tilde{\theta}$ of $\tilde{D}_{eq}$ with respect to $(s_1, ..., s_l)$ is given by $\tilde{\theta} = (1 - t)\theta_0$, and thus by ($\kappa$) in subsection 2.1, the corresponding equivariant curvature matrix $\tilde{\kappa}$ is given by

$$\tilde{\kappa}(X) = d\tilde{\theta} + \tilde{\theta} - i_X \tilde{\theta} + \ell(X)$$

for $X = (X_{ij}) \in u(l)$. Recall that $\ell(X) = (\ell_{ij}(X))_{ij}$ is defined by $L^E_X s_i = \sum_{j=1}^l \ell_{ji}(X)s_j$. For later use, we rewrite it as

$$\tilde{\kappa}(X) = -dt \land \theta_0 + \kappa_t(X),$$

$$\kappa_t(X) = (1 - t)d\theta_0 + (1 - t)^2\theta_0 \land \theta_0 - (1 - t)i_X \theta_0 + \ell(X).$$

By the definition of the equivariant Bott-difference form,

$$c^l(D^0_{eq}, D^1_{eq}) = \rho_* c^l(\tilde{\kappa})$$

$$= \left(\frac{\sqrt{-1}}{2\pi}\right)^l \rho_* \det\tilde{\kappa}$$

$$= -\left(\frac{\sqrt{-1}}{2\pi}\right)^l \sum_{j=1}^l \int_0^1 \det Q_j dt,$$

where $Q_j$ is the matrix obtained from $\kappa_t$ by replacing the $j$-th column by that of $\theta_0$. In the following, we compute $\det Q_j$. Computing the $(i, j)$-entry of $d\theta_0$, $\theta_0 \land \theta_0$, $\ell(X)$ and $i_X \theta_0$, we have

$$(d\theta_0)_{ij} = -\left(\frac{1}{\|z\|^2}d\bar{z}_j + \bar{z}_jd\left(\frac{1}{\|z\|^2}\right)\right) \land dz_i$$

$$(\theta_0 \land \theta_0)_{ij} = \frac{1}{\|z\|^4} \bar{z}_jdz_i \land \left(\sum_{k=1}^l \bar{z}_kdz_k\right)$$

$$(i_X \theta_0) = -\frac{\bar{z}_j}{\|z\|^2} \sum_{k=1}^l X_{ik}z_k.$$  

$$\ell(X)_{ij} = X_{ij}.$$  

We set the matrices $\tau(X)$ and $\eta(X)$ as follows;

$$\tau(X)_{ij} := -(1 - t)\frac{1}{\|z\|^2}d\bar{z}_j \land dz_i + X_{ij}$$

$$\eta(X)_{ij} := -(1 - t)\bar{z}_jd\left(\frac{1}{\|z\|^2}\right) \land dz_i + (1 - t)^2(\theta_0 \land \theta_0)_{ij} + (1 - t)(i_X \theta_0)_{ij}.$$  

Then, $\kappa_t(X) = \tau(X) + \eta(X)$. Denoting $k$-th column of $\kappa_t(X)$ and $\tau(X), \eta(X)$ by $\kappa_t(X)_{(k)}$ and $\tau(X)_{(k)}, \eta(X)_{(k)}$ respectively, the matrix $Q_j$ may be expressed as follows:

$$\det Q_j = \det[\kappa_t(X)_{(1)}, ..., \theta_{0(j)}, ..., \kappa_t(X)_{(l)}].$$
We decompose this determinant with respect to the columns $\tau(X)^{(k)}, \eta(X)^{(k)}$ by using multilinearity of determinant. Note that, if more than two columns of $\eta(X)$ appear in the determinant obtained from the decomposed term, the term vanishes. Thus, we have

$$\det Q_j = \det R_j + \sum_{k \neq j} \det R_{jk},$$

where

$$R_j := [\tau(X)^{(1)}, \ldots, \theta_0^{(j)}, \ldots, \tau(X)^{(l)}]$$

$$R_{jk} := [\tau(X)^{(1)}, \ldots, \theta_0^{(j)}, \ldots, \eta(X)^{(k)}, \ldots, \tau(X)^{(l)}].$$

By the definition, we see that $\det R_{jk} = -\det R_{kj}$. Directly computing, we have

$$c^l(D_{eq}^0, D_{eq}^1) = -\left(\frac{\sqrt{-1}}{2\pi}\right)^l l! \left\{ \sum_{j=1}^{l-1} \int_0^1 \det R_j dt + \int_0^1 \sum_{j=1}^{l-1} \sum_{k \neq j} \det R_{jk} dt \right\}$$

$$= -\left(\frac{\sqrt{-1}}{2\pi}\right)^l l! \sum_{j=1}^{l-1} \int_0^1 \det R_j dt$$

$$= -C_l \sum_{j=1}^{l-1} \frac{\Phi_j(z) \wedge \Phi(z)}{||z||^2} + \text{(terms with } X_{ij}),$$

(2)

where

$$\Phi(z) = dz_1 \wedge \cdots d z_l$$

$$\Phi_j(z) = (-1)^{i-1} z_1 dz_1 \wedge \cdots \wedge \widehat{dz_i} \wedge \cdots \wedge d z_l$$

and

$$C_l = (-1)^{(l-1)/2} \frac{(l-1)!}{(2\pi)^l \sqrt{-1}^l}.$$

Thus, we have $-\int_{S^{2l-1}} c^l(D_{eq}^0, D_{eq}^1) = 1$, since $C_l \sum_{j=1}^{l-1} \frac{\Phi_j(z) \wedge \Phi(z)}{||z||^2}$ coincides the Bochner-Martinelli kernel $\beta_l$ on $\mathbb{C}^l$ (see [?]).

3.4 Explicit formula of universal $U(l)$-equivariant Thom form

We give an explicit formula of universal $U(l)$-equivariant Thom form

$$(0, c^l_{eq}(D_{eq}^1), c^l_{eq}(D_{eq}^0, D_{eq}^1)) \in \Omega_{U(l)}^{2l}(W, W_0).$$

In particular, higher terms in (3) are precisely determined.

We provide some notations to simplify a calculation. Let $V$ be a complex vector space of dimension $l$ with a basis $e_1, \ldots, e_l$. For any anticommutative $\mathbb{Z}$-graded algebra $A$, we consider the algebra $A \otimes \wedge^* V$ with the following wedge product; $(\alpha \otimes \xi) \wedge (\beta \otimes \eta) := (\alpha \wedge \beta) \otimes (\xi \wedge \eta)$. It is easy to see the following lemma:
(1) Let \( \omega_i = \sum_{k=1}^{l} \omega_{ik} \otimes e_k \), then
\[
\omega_1 \wedge \cdots \wedge \omega_l = \sum_{\sigma \in \mathfrak{S}_l} \text{sgn}(\sigma) (\omega_{\sigma(1)} \wedge \cdots \wedge \omega_{\sigma(l)}) \otimes (e_1 \wedge \cdots \wedge e_l)
\]
(2) Let \( \alpha = \sum_{k=1}^{l} \alpha_k \otimes e_k \) and \( \beta = \sum_{k=1}^{l} \beta_k \otimes e_k \in \mathcal{A} \otimes \wedge^s V \) with \( \text{deg}(\alpha_k) = s \) and \( \text{deg}(\beta_k) = t \), then
\[
\alpha \wedge \beta = (-1)^{st} \beta \wedge \alpha
\]
We write \([l] := \{1, 2, \cdots, l\} \). If \( I \) is a subset of \([l]\), we denote by \( e_I \) the product \( e_{i_1} \wedge \cdots \wedge e_{i_p} \) where we write \( I = \{i_1, i_2, \ldots, i_p\} \) with \( i_1 < i_2 < \cdots < i_p \). Denote by \( |I| = p \), the cardinality of \( I \). For \( I = \{i_1, i_2, \ldots, i_p\} \) and \( I' = \{i_1', i_2', \ldots, i_p'\} \) in \([l]\), we set 
\[
\epsilon_{(I, I')} := (-1)^\sum_{s+t=i} (i_s + t_s).
\]
Let \( X = [X_{ij}] \in \mathfrak{u}(l) \), and denote by \( X_{I, I'} \) the retainer minor of \( X \) with respect to \( I \) and \( I' \): \( X_{I, I'} = \det[X_{i_s, i'_t}]_{s, t \leq p} \). If \( 1 \leq k \leq l \) and \( k \not\in J \), we denote by \( \epsilon(k, J) \) the sign such that \( e_k \wedge e_J = \epsilon(k, J) e_{\{k\} \cup J} \). Put
\[
\gamma(k, I, J) = (-1)^{\frac{|J|(|J|-1)}{2}} \left( \frac{\sqrt{-1}}{2\pi} \right)^l |J|! \epsilon(k, J).
\]

Theorem 3.15. For \( X \in \mathfrak{u}(l) \), we have
\[
\chi_{eq}(X) := c^l(D_{eq}^1) = \left( \frac{\sqrt{-1}}{2\pi} \right)^l \det X
\]
\[
\beta_{eq}(X) := c^l(D_{eq}^0, D_{eq}^1) = \sum_{k, I, J} \gamma(k, I, J) \sum_{I', J'} \epsilon_{(I, I')} X_{I, I'} d\bar{z}_k d\bar{z}_I \wedge d\bar{z}_{J'} \left( \frac{1}{|z|^{2(|J|+1)}} \right)
\]
where for \( 1 \leq k \leq l \), the sets \( I, J \) vary over the subsets of \([l]\) such that \( \{k\} \cup I \cup J \) is a partition of \([l]\), and \( I' \) and \( J' \) vary over the subsets of \([l]\) such that \( |I| = |I'| \) and \( I' \cup J' \) is a partition of \([l]\).

Proof. Let \( \theta_1 \) and \( \kappa_1 \) be the connection matrix and the corresponding equivariant curvature matrix with respect to the frame \( (s_1, \ldots, s_l) \). Since \( \theta_1 = 0 \),
\[
\kappa_1(X) = d\theta_1 + \theta_1 \wedge \theta_1 - \iota_X \theta_1 + \ell(X) = \ell(X) = X.
\]
Thus, \( c^l(D_{eq}^1) = c^l(X) = \left( \frac{\sqrt{-1}}{2\pi} \right)^l \det X \). Next, we compute \( c^l(D_{eq}^0, D_{eq}^1) \). Set \( Y = -\frac{1}{1-t} X \). Then
\[
\det R_k = \det [\tau(X)^{(1)}, \ldots, \theta_0^{(k)}, \ldots, \tau(X)^{(l)}] = (-1)^{(1-t)^l - 1} \frac{1}{|z|^{2l}} P
\]

19
with

\[ P = \sum_{\sigma \in \mathcal{G}_l} \text{sgn}(\sigma)(d\zeta_1 \wedge d\zeta_{\sigma(1)} + Y_{1\sigma(1)}) \wedge \cdots \wedge \zeta_k d\zeta_{\sigma(k)} \wedge \cdots \wedge (d\zeta_i \wedge d\zeta_{\sigma(l)} + Y_{l\sigma(l)}) \]

\[ = \sum_{\sigma \in \mathcal{G}_l} \text{sgn}(\sigma) \sum_{I,J} (d\zeta_{j_1} \wedge d\zeta_{(j_1)}) \wedge \cdots \wedge (\zeta_k d\zeta_{(k)}) \wedge \cdots \wedge (d\zeta_{j_q} \wedge d\zeta_{(j_q)}) Y_{i_1 \sigma(i_1)} \cdots Y_{i_p \sigma(i_p)} \]

\[ = \sum_{I,J} (-1)^{\frac{|I|(|I|-1)}{2}} \epsilon(k, J) \cdot \zeta_k d\zeta_J \cdot \sum_{\sigma \in \mathcal{G}_l} \text{sgn}(\sigma) d\zeta_{(j_1)} \wedge \cdots \wedge d\zeta_{(k)} \wedge \cdots \wedge d\zeta_{(j_q)} Y_{i_1 \sigma(i_1)} \cdots Y_{i_p \sigma(i_p)}, \]

where \( \{k\}, I = \{i_1, i_2, \ldots, i_p\} \) and \( J = \{j_1, j_2, \ldots, j_q\} \) is a partition of \([l]\). Set

\[ Z = \sum_{i=1}^l d\zeta_i \otimes e_i, \quad Y_j = \sum_{i=1}^l Y_{ji} \otimes e_i. \]

By Lemma ??, we see

\[ \sum_{\sigma \in \mathcal{G}_l} \text{sgn}(\sigma) d\zeta_{(j_1)} \wedge \cdots \wedge d\zeta_{(k)} \wedge \cdots \wedge d\zeta_{(j_q)} Y_{i_1 \sigma(i_1)} \cdots Y_{i_p \sigma(i_p)} \otimes (e_1 \wedge \cdots \wedge e_l) \]

\[ = Z \wedge \cdots \wedge Y_{i_1} \wedge \cdots \wedge Z \wedge \cdots \wedge Y_{i_p} \wedge \cdots \wedge Z \]

\[ = (-1)^m (Y_{i_1} \wedge \cdots \wedge Y_{i_p}) \wedge (Z \wedge \cdots \wedge Z) \]

where \( m = \sum_{s=1}^p i_s - \frac{1}{2} p(p + 1) \). Note that

\[ Y_{i_1} \wedge \cdots \wedge Y_{i_p} = \sum_{I'} Y_{I', I'} e_{I'} \cdot Z \wedge \cdots \wedge Z = \sum_{J'} (q + 1)! d\zeta_{J'} \otimes e_{J'}, \]

where \( I' \) runs over subsets of \( p \) elements in \([l]\), \( J' \) runs over subsets of \( (l - p) \) elements in \([l]\), and \( Y_{I', I'} \) is a retainer minor of \([Y_{ij}]\) with respect to \( I \) and \( I' \). Then

\[ (-1)^m (Y_{i_1} \wedge \cdots \wedge Y_{i_p}) \wedge (Z \wedge \cdots \wedge Z) \]

\[ = (-1)^m \sum_{I'} Y_{I', I'} \sum_{J'} (q + 1)! d\zeta_{J'} \otimes (e_{I'} \wedge e_{J'}) \]

\[ = (q + 1)! \sum_{I', J'} (-1)^{\sum_{s=1}^p (i_s + 1)} Y_{I', J'} d\zeta_{J'} \otimes (e_1 \wedge \cdots \wedge e_l). \]

Since \( Y_{ii'} = -\frac{\|z\|^2}{1-t} X_{ii'} \), we have

\[ \det R_k = \sum_{I,J} \epsilon(k, J) (-1)^{\frac{|I|(|I|-1)}{2} + l(|J| + 1)!} \sum_{I', J'} \epsilon(I', I') X_{I', J'} \zeta_k d\zeta_J \wedge d\zeta_{J'} \frac{1}{\|z\|^2(|J| + 1)} (1 - t)^{|J|}. \]
Hence,
\[
c^l(D^0_{eq}D^1_{eq}) = -\left(\frac{\sqrt{-1}}{2\pi}\right)^l \sum_{k=1}^l \int_0^1 \det R_k \, dt
\]
\[
= \sum_{k,l,l'} k(l,l',l') \sum_{I,J} \epsilon(I,l') \epsilon(l,l') X_{I,I'} \frac{\bar{z}_k d\bar{z}_l \wedge dz_{l'}}{\|z\|^{2(|l|+1)}}.
\]

\[\square\]

**Example 3.16.** For small \(l\), the equivariant Bochner-Martinelli kernel is computed as follows.

1. In the case of \(l = 1\),
\[
\beta_{eq}(X) = \frac{\sqrt{-1}}{2\pi} \frac{\bar{z} dz}{\|z\|^2} = \frac{\sqrt{-1}}{2\pi} \frac{dz}{z}.
\]
This is nothing but the original (non-equivariant) kernel.

2. In the case of \(l = 2\), for \(X = (X_{ij}) \in u(2)\),
\[
\beta_{eq}(X) = \left(\frac{\sqrt{-1}}{2\pi}\right)^2 \left\{ \frac{\bar{z}_1 d\bar{z}_2 \wedge dz_1 \wedge dz_2}{\|z\|^4} - \frac{\bar{z}_2 d\bar{z}_1 \wedge dz_1 \wedge dz_2}{\|z\|^4} + X_{1,1} \frac{\bar{z}_2 dz_2}{\|z\|^2} - X_{1,2} \frac{\bar{z}_2 dz_1}{\|z\|^2} - X_{2,1} \frac{\bar{z}_1 dz_2}{\|z\|^2} + X_{2,2} \frac{\bar{z}_1 dz_1}{\|z\|^2} \right\}.
\]
To be more specific, we see the real part of this form: Set \(z_1 = x_1 + \sqrt{-1} y_1\), \(z_2 = x_2 + \sqrt{-1} y_2\) and
\[
X = \begin{pmatrix} \sqrt{-1}A & B + \sqrt{-1}C \\ -B + \sqrt{-1}C & -1D \end{pmatrix},
\]
where \(A,B,C,D\) are real numbers. Then, a simple computation shows
\[
\text{Re}(\beta_{eq}(X))
\]
\[
= \frac{1}{2\pi^2\|z\|^4} \left[ (x_1 dx_2 \wedge dy_1 \wedge dy_2 + x_2 dx_1 \wedge dy_1 \wedge dy_2 - y_1 dx_1 \wedge dx_2 \wedge dy_1 - y_2 dx_1 \wedge dx_2 \wedge dy_1) + \frac{1}{4\pi^2\|z\|^2} \left( -Ax_2 dy_2 + Ay_2 dx_2 + Bx_1 dx_2 + By_1 dy_2 - Bx_2 dx_1 - By_2 dy_1 + Cx_1 dy_2 - Cy_1 dx_2 + Cx_2 dy_1 - Cy_2 dx_1 - Dx_1 dy_1 + Dy_2 dx_2 \right) \right].
\]
This form coincides with the angular form for \(so(4)\) of Proposition 4.10 in Paradan-Vergne [?].
3.5 Explicit formula of $G$-equivariant Thom form

In this subsection, applying the equivariant Chern-Weil map [?, ?] to Theorem ??, we obtain a formula expressing the equivariant Thom form for general $G$-vector bundles.

**Definition 3.17.** Let $M$ be a manifold with a Lie group $G$-action. $\alpha \in \Omega^*(M)$ is called horizontal if $\iota_X \alpha = 0$ for any $X \in \mathfrak{g}$. We denote by $\Omega^*(M)_{\text{hor}}$ the subalgebra formed by the differential forms that are horizontal. Also we define the algebra of the basic differential forms as follows;

$$\Omega^*(M)_{\text{basic}} := (\Omega^*(M)_{\text{hor}})^G$$

Let $\pi : P \to B$ be a principal $G$-bundle. And suppose $G$ acts on a manifold $F$. For the associated bundle $F = P \times_G F$, the Chern-Weil map in non-equivariant case gives the following isomorphism;

$$\phi^F_\theta : \Omega^*_G(F) \xrightarrow{\sim} \Omega^*(F),$$

where $\theta$ is a connection form of $P$. In more details, for a $G$-equivariant form $\alpha$, $\phi^F_\theta(\alpha)$ is equal to the projection of $\alpha(\Omega) \in \Omega(P \times F)^G$ on the basic space $\Omega(P \times F)_{\text{basic}} \xrightarrow{\sim} \Omega(F)$, where $\Omega$ is the curvature of the connection $\theta$. We give the equivariant version of this construction in the following.

Let $K$ and $G$ be two compact Lie groups and $P$ be a smooth manifold. We assume that $K \times G$ acts on $P$ as follows; $(k, g)(y) := kyg^{-1}$, for $k \in K$, $g \in G$. And $G$ acts on $P$ freely. Then, $B = P/G$ is a manifold provided with a left action of $K$. There is $K$-invariant connection $\theta$ of $P$, since $K$ is compact. Then, for a $K$-invariant connection $\theta$, $K$-equivariant curvature of $P$ is defined as follows;

$$\tilde{\Omega} := d_K \theta + \frac{1}{2} [\theta \wedge \theta],$$

where $d_K$ is $K$-equivariant differential. Using this, we consider the equivariant Chern-Weil map;

$$\phi^F_\tilde{\theta} : \Omega^*_K(F) \xrightarrow{\sim} \Omega^*_K(F).$$

It is defined as follows. For a $G$-equivariant form $\alpha$ on $F$, $\phi^F_\tilde{\theta}(\alpha)$ is equal to the projection of $\alpha(\tilde{\Omega}) \in \Omega^*_K(P \times F)^G$ onto the basic space $\Omega^*_K(P \times F)_{\text{basic}} \xrightarrow{\sim} \Omega^*_K(F)$.

**Proposition 3.18.** The equivariant Chern-Weil map above satisfies the following condition;

$$\phi^F_\tilde{\theta} \circ d_G = d_K \circ \phi^F_\tilde{\theta}.$$
By using this, we may give the $G$-equivariant Thom form as follows;

\[(0, \phi_{\theta}^c \{0\} \circ D_{eq}(D_{eq}^0, D_{eq}^1)) \in \Omega^2_{G}(W, W_0)\]

It follow from Proposition ?? that this form is closed. Then, we denote by $c_{\Sigma}^G(\pi^*E, s_\Delta)_{eq}$ the class of this form, where $s_\Delta : E \to \pi^*E$ is the diagonal section and $\Sigma$ is the zero section of $E$. It is not difficult to show that the equivariant fiber integration is compatible with the equivariant Chern-Weil map. Thus, we have the following formula:

**Theorem 3.19.** In the above situation, we have

$$\Psi_{eq}^E = c_{\Sigma}^G(\pi^*E, s_\Delta)_{eq},$$

where $\Psi_{eq}^E$ is the $G$-equivariant Thom class for $E$.

## 4 Equivariant Riemann-Roch Theorem

In this last section, we show a version of equivariant Riemann-Roch theorem in our setting. Indeed, it is entirely parallel to the description in non-equivariant case (cf. [?]).

### 4.1 Chern character and Todd class

Let $G$ be a compact manifold and $E \to M$ be a $G$-equivariant vector bundle of rank $l$. For a $G$-equivariant connection $\nabla_{eq}$ for $E$, let $K_{eq}$ denote its curvature and set $A = (\sqrt{-1}/2\pi)K_{eq}$.

For $G$-equivariant connection $\nabla_{eq}$, the equivariant Chern character form and Todd form is defined as follows;

$$\text{ch}^*(\nabla_{eq}) := \text{tr}(e^A)$$

$$\text{td}(\nabla_{eq}) := \text{det} \left( \frac{A}{I - e^{-A}} \right)$$

Note that $I - e^{-A}$ is divisible by $A$ and the result is invertible so that

$$\text{td}^{-1}(\nabla_{eq}) = \text{det} \left( \frac{I - e^{-A}}{A} \right)$$

In the same way of the Chern form, we may easily show that these form is closed and the classes of these form is independent of the choice of equivariant connections. Note that the constant term in $\text{td}(\nabla_{eq})$ is 1 and that $\text{td}(\nabla_{eq})$ can be expressed as a series in $c^l(\nabla_{eq})$. Then, we have the following formula;

$$\sum_{i=0}^l (-1)^i \text{ch}^*(\bigwedge^i \nabla_{eq}) = c^l(\nabla_{eq}) \cdot \text{td}(\nabla_{eq})^{-1},$$

23
where $\nabla_{eq}^*$ denotes the connection for $E^*$ dual to $\nabla_{eq}$ and $\wedge^i \nabla_{eq}^*$ the connection for $\wedge^i E^*$ induced by $\nabla_{eq}^*$. Here we set $\wedge^0 E = \mathbb{C} \times M$ and $\wedge^0 \nabla_{eq}^* = d_{eq}$, the twisted de Rham differential.

4.2 Equivariant characteristic forms for virtual bundles

Let $E_i$ ($i = 0, \ldots, q$) be $G$-equivariant complex vector bundles. We may consider the virtual bundle $\xi = \sum_{i=0}^q (-1)^i E_i$ (as an element of $K$-group of $G$-equivariant vector bundles on $M$) and a family of equivariant connections $\nabla_{eq}^* = (\nabla_{eq}^{(0)}, \ldots, \nabla_{eq}^{(q)})$, where $\nabla_{eq}^{(0)}$ is a $G$-equivariant connection for $E_i$. We set

$$c^*(\nabla_{eq}^*) = \prod_{i=0}^q c^*(\nabla_{eq}^{(i)})^{\epsilon(i)} \quad \text{and} \quad \text{ch}^*(\nabla_{eq}^*) = \sum_{i=0}^q (-1)^i \text{ch}(\nabla_{eq}^{(i)}),$$

where $\epsilon(i) = (-1)^i$. In general, for a symmetric series, we may define a form $\phi(\nabla_{eq}^*)$. It is closed and its class $\phi(\xi)$ is in $H^*_G(M)$. For two families of connections $(\nabla_{eq}^*)_\nu = ((\nabla_{eq}^{(0)})_\nu, \ldots, (\nabla_{eq}^{(q)})_\nu)$, $\nu = 1, 2$, the same argument for non-virtual version may define the Bott difference form $\phi((\nabla_{eq}^*)_0, (\nabla_{eq}^*)_1)$. From this, in the same way of non-virtual version, we easily see that $\phi(\xi) = [\phi(\nabla_{eq}^*)]$ is independent of the choice of a families of connections.

We may also define the equivariant characteristic classes for virtual bundle in the equivariant Čech-de Rham cohomology as in section 2.1. It is sufficient to consider coverings $U$ consisting of two open sets $U_0$ and $U_1$ for the sake of argument in the following. Then, taking a family of connections $(\nabla_{eq}^*)_\nu = ((\nabla_{eq}^{(0)})_\nu, \ldots, (\nabla_{eq}^{(q)})_\nu)$ for $\xi$ on each $U_\nu$, $\nu = 0, 1$, for the collection $(\nabla_{eq}^*)_\bullet = ((\nabla_{eq}^*)_0, (\nabla_{eq}^*)_1)$, a cochain $\phi((\nabla_{eq}^*)_\bullet)$ in $\Omega^*_G(U)$ is defined as follows;

$$\phi^i((\nabla_{eq}^*)_\bullet) = \phi^i((\nabla_{eq}^*)_0, (\nabla_{eq}^*)_1)$$

It is in fact a cocycle and defines a class $[\phi^i((\nabla_{eq}^*)_\bullet)]$ in $H^*_G(U)$. It does not depend on the choice of the collection of families of connections $(\nabla_{eq}^*)_\bullet$ and corresponds to the class $\phi(\xi)$ under the isomorphism $H^*_G(U) \simeq H^*_G(M)$.

4.3 Equivariant Riemann-Roch Theorem

Let $M$ be as above, $s$ a $G$-invariant section in $M$. Let $S$ denote the zero set of $s$ (note that $S$ is also $G$-invariant). Letting $U_0 = M \setminus S$ and $U_1$ a $G$-invariant neighborhood of $S$, we consider the $G$-invariant covering $U = \{U_0, U_1\}$. We set $\lambda_{E^*} = \sum_{i=0}^l (-1)^i \wedge^i E^*$. Let $\nabla_0$ be an $s$-trivial $G$-equivariant connection for $E$ on $U_0$ and $\nabla_1$ an arbitrary $G$-equivariant connection for $E$ on $U_1$. Consider the Koszul complex associated to $(E, s)$ (for more details, see [?]):

$$0 \longrightarrow \wedge^l E^* \overset{d_s}{\longrightarrow} \cdots \overset{d_s}{\longrightarrow} \wedge^1 E^* \overset{d_s}{\longrightarrow} \wedge^0 E^* \longrightarrow 0$$
which is exact on $U_0$. It is easy to show that the family $\bigwedge^i(\nabla_{eq}^*) = (\bigwedge^i(\nabla_{eq}^*)_0, \ldots, \bigwedge^0(\nabla_{eq}^*)_0)$ is compatible with the above sequence on $U_0$. The fact that $\chi^*(\bigwedge^i(\nabla_{eq}^*)_0) = 0$ follows from this. Then, we have the localization $\chi_S^*(\lambda_E^*, s)_{eq}$ in $H^*_G(M, M \setminus S; \mathbb{C})$, which is represented by the cocycle

$$\chi^*(\bigwedge^i(\nabla_{eq}^*)_*) = (0, \chi^*(\bigwedge^i(\nabla_{eq}^*)_1), \chi^*(\bigwedge^i(\nabla_{eq}^*)_0, \bigwedge^i(\nabla_{eq}^*)_1))$$

We also have the inverse equivariant Todd class $td^{-1}(E)_{eq}$, which is represented by the cocycle

$$td^{-1}(\bigwedge^i(\nabla_{eq}^*)_*) = (td^{-1}(\bigwedge^i(\nabla_{eq}^*)_0), td^{-1}(\bigwedge^i(\nabla_{eq}^*)_1), td^{-1}(\bigwedge^i(\nabla_{eq}^*)_0, \bigwedge^i(\nabla_{eq}^*)_1))$$

We give some definitions for the theorem in the following. Let $\rho : \mathbb{R} \times U_{01} \to U_{01}$ be the projection and we consider the connection $\tilde{\nabla}_{eq} = (1 - t)\rho^*(\nabla_{eq})_0 + t\rho^*(\nabla_{eq})_1$ for $\rho^*E$. Let $\bigwedge^i(\nabla_{eq}^*)_{\nu}$ denote the family of connections $(\bigwedge^i(\nabla_{eq}^*)_0, \ldots, \bigwedge^i(\nabla_{eq}^*)_1)$ on $U_{\nu}$, for $\nu = 0, 1$. Also we denote by $\bigwedge^i(\tilde{\nabla}_{eq}^*)$ the family $(\bigwedge^i(\tilde{\nabla}_{eq}^*)_0, \ldots, \bigwedge^i(\tilde{\nabla}_{eq}^*)_1)$. Let $\rho' : [0, 1] \times U_{01} \to U_{01}$ be the restriction of $\rho$.

**Theorem 4.1.** In the above situation, we have

$$\chi^*(\bigwedge^i(\nabla_{eq}^*)_*) = c'(\bigwedge^i(\nabla_{eq}^*)_*) - td^{-1}(\bigwedge^i(\nabla_{eq}^*)_*) + D_{eq}\tau$$

where $\tau = (0, 0, \tau_0)$, $\tau = \rho'_*(c'(\rho^*(\nabla_{eq}^*)_0, \nabla_{eq}) \cdot d_{eq}td^{-1}(\rho^*(\nabla_{eq}^*)_1, \nabla_{eq})$.

The following corollary follows immediately from this.

**Corollary 4.2.** We have

$$\chi_S^*(\lambda_E^*, s)_{eq} = c'_S(E, s) \cdot td^{-1}(E)_{eq}$$

Also, as an applications of the above, we may get the equivariant universal localized Riemann-Roch theorem for embeddings by using the result in the previous section. Let $\pi : E \to M$ be a $G$-equivariant vector bundle of rank $l$. We have the $G$-equivariant Thom class $\Psi_{eq}^E$ and the Thom isomorphism

$$T_E : H^*_G(M) \to H^{*+2i}_G(E, E \setminus \Sigma)$$

which is given by $T_E(\alpha) = \Psi_{eq}^E \cdot \pi^*\alpha$. Since $\Psi_{eq}^E = c'_S(\pi^*E, s\Delta)_{eq}$, applying the above Corollary to $\pi^*E$ and $s\Delta$, we have:

**Theorem 4.3** (Equivariant universal localized RR for embeddings).

$$\chi_{eq}^*(\lambda_{\pi^*E^*}, s\Delta)_{eq} = \Psi_{eq}^E \cdot td^{-1}(\pi^*E)_{eq} = T_E(td^{-1}(E)_{eq})$$
