19 **Abstract**

20 Andrastins are meroterpenes isolated from *Penicillium* sp. FO-3929 that display highly potent

21 inhibitory activities toward protein farnesyltransferase. Structurally, they possess a unique steroidal

22 tetracyclic skeleton (the ABCD-ring) with three contiguous quaternary stereocenters on the C-ring.

23 Herein, we describe our nitrile cyclization-based approach to the stereoselective construction of the

24 BCD-ring system of andrastins, which contains three contiguous quaternary stereocenters on the

25 C-ring and the correct oxidation states of the D-ring.

26

Keywords: andrastins / antitumor antibiotics / carbocycles / cyclization / ene reaction / nitriles / quaternary stereocenters

Introduction

Andrastins A–D (**1–4**) are fungal meroterpenes that were isolated from the cultured broth of *Penicillium* sp. FO-3929 by Ōmura and co-workers in 1996.^{1–4} These compounds exhibit potent inhibitory activities toward protein farnesyltransferase (IC₅₀, 13.3–47.1 μM).^{2,4} Because protein farnesyltransferase is essential for maturation of the Ras oncogene protein, andrastins are considered promising anti-cancer drug candidates.⁵ Structurally, andrastins A–D (**1–4**) share a unique steroidal 6-6-6-5 tetracyclic skeleton (the ABCD-ring), differing only in the substituent at the angular C10 position and the oxidation state at C3 of the A-ring (Scheme 1a). Their distinctive biological and pharmacological properties, coupled with their complex chemical structures, have made andrastins attractive targets for chemical synthesis. As a result, a number of research groups have been involved in synthetic studies of andrastins.^{6–10} Recently, the first total synthesis of (±)-andrastin D (**4**) was achieved by Newhouse, Maimone, and co-workers via a biomimetic polyene cyclization and a diketene annulation as the key steps.⁶ Additionally, Toyota, Ihara, and co-workers constructed the tetracyclic framework of andrastins that featured a stereoselective intramolecular Diels–Alder reaction and a carbonyl ene reaction.^{7,8} Matsuya and co-workers reported an alternative intramolecular Diels–Alder approach to the tetracyclic skeleton of andrastins.^{9,10} In order to ultimately understand the detailed mode of action of andrastins at the molecular level, we have engaged in synthetic studies of them. Herein, we report a novel nitrile cyclization-based approach for the stereoselective construction of the BCD-ring system with three contiguous quaternary asymmetric stereocenters, the common substructure in andrastins.

53 Results and discussion

54 From a synthetic perspective, the major challenges posed by andrastins **1–4** are (1) construction of
55 the stereochemically dense C-ring, which has three contiguous quaternary stereocenters at the C8,
56 C13, and C14 positions, and (2) construction of the five-membered D-ring, which has a sensitive
57 1,3-diketone moiety. To overcome these challenges, we designed a synthetic strategy based on
58 nitrile cyclizations (Scheme 1b). To confirm our strategy, tricyclic model compound **10** was chosen
59 as the initial target. We planned to synthesize **10** from cyclic nitrile **5** (the B-ring model),
60 whereupon a quaternary stereocenter at the C8 position would be constructed by the intramolecular
61 conjugate addition of α,β -unsaturated esters bearing an alkanenitrile side chain.¹¹ An intramolecular
62 ene reaction of nitrile **6** would construct the C-ring structure **8** after isomerization of the olefin in
63 the ene product **7** and the subsequent hydrolysis of the resulting imine moiety. In contrast to
64 carbonyl ene reactions that have been widely used in organic synthesis,¹² cyano ene reactions have
65 been less frequently explored due to the poor reactivity of the cyano group as an enophile.^{13–15}
66 However, we anticipated that the cyano ene reaction of the simple non-activated alkanenitrile **6**
67 would proceed upon activation by a Brønsted or Lewis acid because of an entropically favored
68 intramolecular process. Lastly, formation of the D-ring with the desired oxidation states would be
69 achieved through a similar intramolecular cyano ene reaction of β -ketonitrile **9** to afford tricyclic
70 compound **10**.

71 Our synthesis commenced with the preparation of cyano alkene **6** (Scheme 2). Alkylation of
72 ethyl isobutyrate (**11**) with 5-bromo-1-pentene followed by reduction with LiAlH_4 gave primary
73 alcohol **12**, which underwent cobalt-catalyzed hydrocyanation¹⁶ to furnish secondary nitrile **14** with
74 complete regioselectivity. The product **14** was then converted to α,β -unsaturated ester **15** through a
75 Swern oxidation and subsequent Horner–Wadsworth–Emmons olefination. Treatment of **15** with
76 potassium bis(trimethylsilyl)amide (KHMDs) in THF–toluene at $-78\text{ }^\circ\text{C}$ induced an intramolecular
77 conjugate addition¹¹ to give cyclization product **5** (the B-ring) with the quaternary stereocenter at
78 the C8 position (96% yield) with high diastereoselectivity (dr = 95:5). The high stereoselectivity of

this cyclization can be explained through the chelated transition state model, wherein the keteniminate and α,β -unsaturated ester are both oriented equatorially in an antiparallel dipolar arrangement (Supplementary Information, Scheme S1). The stereochemistry of **5** was confirmed by NOESY experiments. Chemoselective reduction of the ester over the cyano group in **5** with diisobutylaluminum hydride (DIBAL-H) followed by Swern oxidation produced aldehyde **16**. This compound was converted to cyano alkene **6** as inseparable geometric isomers (68:32) in three steps, i.e., addition of methyl Grignard reagent, tetrapropylammonium perruthenate (TPAP) oxidation¹⁷ of the resulting alcohol, and Wittig olefination of the resulting methyl ketone.

[Please insert Scheme 2, single column size]

With nitrile **6** in hand, we examined the key ene reaction for the C-ring formation (Scheme 3). Upon treatment of **6** with methanesulfonic acid (MsOH) (10 equiv.) in 1,2-dichloroethane at 80 °C, the intramolecular ene reaction of nitrile **6** and the subsequent isomerization of the olefin occurred smoothly. After the disappearance of **6**, which was monitored by TLC, the solvent was removed by evaporation, and the resulting mixture containing α,β -unsaturated iminium **19** and MsOH was hydrolyzed at 80 to 100 °C to afford enone **8** (86% yield). Thus, this intramolecular cyano ene reaction proved to be a powerful method for the formation of a cyclic enone because the C–C bond forming reaction proceeded at the sterically congested neopentyl position. At present, we assume that the MsOH-mediated cyclization of **6** proceeded via a cyano ene reaction, although an alternative reaction mechanism¹⁸ involving a cationic cyclization of a nitrilium ion cannot be ruled out.

[Please insert Scheme 3, single column size]

Our next objective was the synthesis of the D-ring cyclization precursor **27** (Scheme 4). Treatment of enone **8** with trimethylsilyl cyanide (TMSCN) in the presence of a trimethylsilyl trifluoromethanesulfonate (TMSOTf) catalyst afforded a diastereomeric mixture of cyanohydrins and their trimethylsilyl (TMS) ethers **20**. Dehydration of the crude products **20** with MsOH yielded the desired unsaturated nitrile **21** along with enone **8** and β -cyano ketone **22**. Construction of the quaternary stereocenter at the C14 position was accomplished by deconjugative alkylation of **21**. Upon treatment of **21** with lithium diisopropylamide (LDA) in THF at $-78\text{ }^{\circ}\text{C}$ followed by addition of benzyloxymethyl chloride (BOMCl), deconjugative alkylation proceeded at the less hindered face of the six-membered ring, i.e., the opposite side of the C8 methyl group, to provide target compound **23** in 82% yield (dr = 92:8) accompanied by γ -alkylation product **24** (14% yield). The stereochemistry of **23** was determined by an NOE experiment of alcohol **25** after removal of the benzyl group in **23**. Alcohol **25** was successfully converted to nitrile **27** as an inseparable mixture of four isomers (dr = 55:26:12:7) by a three-step sequence: (1) partial hydrogenation of the diene in **25** using Pd/C (5%) with concomitant isomerization to afford tetrasubstituted olefin **26**, wherein a minor diastereomer derived from **23** was separated, (2) Swern oxidation of the primary alcohol, and (3) addition of the deprotonated propionitrile to the resulting aldehyde.

[Please insert Scheme 4, double column size]

The final task in the synthesis was the challenging cyano ene reaction for the formation of the D-ring with construction of the quaternary stereocenter at the C13 position (Scheme 5). To this end, alcohol **27** was oxidized with pyridinium chlorochromate (PCC) to β -ketonitrile **9**. The intramolecular cyano ene reaction of **9** proceeded smoothly when treated with BCl_3 (6 equiv.) at room temperature, affording the stable enaminone **28** as a single diastereomer (93% yield). NOESY experiments revealed that **28** possessed the 6,5-*cis*-fused ring system (the CD-ring) with the correct stereostructure. However, enaminone **28** resisted hydrolysis to 1,3-diketone **29** under either acidic

130 or basic conditions. To enhance the reactivity toward hydrolysis as well as to prevent unreactive
131 enaminone formation, we designed the new cyclization precursor **30**, possessing an
132 electron-withdrawing chlorine atom at the α -position of the cyano group. The requisite nitrile **30**
133 was directly synthesized from **27** by a Swern oxidation using an excess amount of oxidant (3
134 equiv.).¹⁹ As expected, the cyclization of **30** with BCl₃ gave α -chloro imine **31**, and the subsequent
135 hydrolysis of **31** with aqueous MsOH afforded diketone **32** (50% yield, two steps). Finally,
136 reductive dechlorination of **32** with Zn–AcOH followed by isomerization of the *exo* olefin yielded
137 the tricyclic compound **10** (84% yield, two steps), thus completing the synthesis of the andrastin
138 BCD-ring system.

140 [Please insert Scheme 5, double column size]

141

142 **Conclusion**

143 In conclusion, we have developed a stereoselective synthetic route to the BCD-ring system of novel
144 protein farnesyltransferase inhibitors, andrastins. The synthesis features (1) construction of the
145 B-ring through a stereoselective conjugate addition of an α -cyano carbanion to an α,β -unsaturated
146 ester, and (2) intramolecular cyano ene reactions for the formation of the C and D-rings. The
147 successful synthesis of the highly sterically congested BCD-ring component having three
148 contiguous stereocenters on the C-ring demonstrates the synthetic utility of nitrile cyclizations (i.e.,
149 an intramolecular conjugate addition and a cyano ene reaction). Further efforts on the total
150 syntheses of andrastins are currently underway.
