ABSTRACT
La-doped A$_x$SnO$_3$ (A = Ba and Sr) have great potential as advanced transparent oxide semiconductors due to their large optical bandgap and relatively high electron mobility. The bandgap of Ba$_{1-x}$Sr$_x$SnO$_3$ solid solution increases from 3.2 eV (BaSnO$_3$) to 4.6 eV (SrSnO$_3$) with x. However, the increase in the bandgap is accompanied by reductions in the electrical conductivity. The versatility in the changes in the electrical properties is not trivial, and property optimization has been challenging. Here, we propose a simple metric for quantifying the transport properties of A$_x$SnO$_3$. We investigated the electron/thermal transport properties of Ba$_{1-x}$Sr$_x$SnO$_3$ solid solution films and their relationship with the lattice distortion. The results suggest that all the transport properties of Ba$_{1-x}$Sr$_x$SnO$_3$ are dominated by the lattice distortion. This phenomenon is attributed to the distortions in the SnO$_6$ octahedron, which consists of the conduction band.

I. INTRODUCTION
Transport properties of perovskite stannate (A$_x$SnO$_3$, A = Ba and Sr) are of great interest in advanced transparent oxide semiconductor technologies. The edge-sharing SnO$_6$ octahedra provide a highly dispersive conduction band that consists of Sn 5s orbitals with a small carrier effective mass ($m^*$), and the A-site elements can change the optical bandgap. For these reasons, the optoelectronic properties of A$_x$SnO$_3$ are highly versatile. For example, n-type BaSnO$_3$ has a cubic structure with an effective mass of $0.4 m_e$ and an optical bandgap of $3.2$ eV. Its single crystal exhibits an excellent carrier electron mobility ($\mu$) of $320$ cm$^2$ V$^{-1}$ s$^{-1}$ at room temperature, which is comparable to classical semiconductors. On the other hand, if Ba is replaced with Sr (SrSnO$_3$), the effective mass reduces to $0.2 m_e$, while the optical bandgap increases to $4.6$ eV. This bandgap can sufficiently transmit deep-UV light (>4.1 eV), which is crucial for DNA sensing. However, despite the smaller $m^*$, the carrier electron mobility of n-type SrSnO$_3$ is significantly lower than that of n-type BaSnO$_3$, which is interesting since the conduction bands of both these materials consist of SnO$_6$ octahedra.

The suppression of carrier electron mobility observed from BaSnO$_3$ ($\mu$ = $320$ cm$^2$ V$^{-1}$ s$^{-1}$) → SrSnO$_3$ ($\mu$ = $60$ cm$^2$ V$^{-1}$ s$^{-1}$) implies that substituting Sr for Ba greatly reduces the mean free path of electrons in A$_x$SnO$_3$. The main scattering mechanism remains unclear but is likely related to the crystallographic transformation from cubic (BaSnO$_3$) to orthorhombic (SrSnO$_3$) structure (Fig. 1), as the SnO$_6$ octahedron will be severely distorted. This will also strongly affect vibrational properties such as thermal conductivity. In this regard, clarifying the effect of substituting Sr for Ba in BaSnO$_3$ on the evolution of both electron and thermal transport properties as well as lattice distortion is crucial for understanding the physical properties of A$_x$SnO$_3$ and controlling their properties for device applications.

In this study, we investigated the effect of lattice distortion on the electron and thermal transport properties of Ba$_{1-x}$Sr$_x$SnO$_3$ solid solution films. Undoped Ba$_{1-x}$Sr$_x$SnO$_3$ solid solution films were used for thermal conductivity measurements, whereas 3% La-doped solid solution [La$_{0.03}$(Ba$_{1-x}$Sr$_x$)$_{0.97}$SnO$_3$] films were used for electron transport property measurements. Thick films...
(thickness: ∼300 nm) were used to relax the strains from the lattice mismatch at the film/substrate interface. The Sr content x in the solid solution was varied from 0 to 1, and the data analysis was performed with a strong emphasis on establishing a relationship between the transport properties and lattice distortion. Crystallographic characterizations showed that the substitution of an A-site ion strongly increases the deviation from a cubic structure. This overcomes the dopant scatterings from the A-site substitution and dominates the changes in the electron transport properties. Thermal conductivity usually decreases with increasing atomic mass. However, although Sr (87.62 amu) is lighter than Ba (137.33 amu), the thermal conductivity of SrSnO3 was much lower than that of BaSnO3, confirming all transport properties are dominated by the deviation from a cubic phase. These contributions reveal a fundamental factor that affects the transport properties in ASnO3, which are of significant importance for engineering their transport properties in various applications.

II. EXPERIMENTAL

Undoped and 3% La-doped Ba1−xSr2SnO3 solid solution films were heteroepitaxially grown on SrTiO3 (001) substrates using pulsed laser deposition (KrF excimer laser, ∼2 J cm−2 pulse−1, 10 Hz). The substrate temperature and oxygen pressure were kept at 800 °C and 10 Pa during the film growth, respectively. The thicknesses of all films were ∼300 nm, which relaxes the strain coming from the lattice mismatch between the film and the substrate. Out-of-plane x-ray Bragg diffraction patterns and reciprocal space mappings (RSMs) were measured with a high-resolution x-ray diffraction (XRD, Cu Kα1, ATX-G, Rigaku Co.) equipment. The lateral grain size (D) of the films was evaluated from the coherence lengths of the diffraction peaks in the RSMs. The powder XRD patterns of the solid solution targets were also measured, and the XRD patterns were analyzed with Rietveld refinement using the Rietan 2000 program.17

The thermal conductivity (κ) of the undoped Ba1−xSr2SnO3 films in the out-of-plane direction was measured using time-domain thermo-reflectance (TDTR, PicoTR, PicoTherm Co.) at room temperature. To prevent the surface roughness from affecting the TDTR signal, the films were annealed in air at 1400 °C for ∼15 min to obtain stepped and terraced surfaces (Fig. S1 in the supplementary material). The electrical conductivity (σ), Hall mobility (μH), and carrier concentration (n) of the La-doped La0.03Ba1−xSr2.97SnO3 films were measured in the in-plane direction at room temperature. The Hall voltage was measured using the conventional d.c. four-probe method with the van der Pauw electrode configuration. The thermopower (S) of the films was measured in the in-plane direction by creating a temperature difference between two edges of the film. Details on our S measurement is available elsewhere.3

III. RESULTS AND DISCUSSION

Figure 2 summarizes the XRD crystallographic analyses. Only intense diffraction peaks of 00lpc of Ba1−xSr2SnO3 solid solution films are seen together with 00l SrTiO3 substrate in the out-of-plane XRD patterns (x = 0, 0.3, 0.6, and 0.9) [Fig. 2(a)]. Note that the XRD characterizations of orthorhombic structure (i.e., SrSnO3) represent a pseudo-cubic unit cell that consists of basis atoms. For example, the pseudo-cubic unit cell of SrSnO3 has Sr × 1, Sn × 1, and O × 3. The scattering vector shifts to the right with increasing x, which indicates a reduction in the pseudo-cubic lattice parameter in the out-of-plane direction. In order to measure the film thickness, we used Pendellösung fringes [Fig. 2(b)]. Figure 2(c) shows a typical RSM of the Ba0.7Sr0.3SnO3 solid solution film around (~103) SrTiO3. The lattice parameter in the out-of-plane direction (c-axis) was 0.41043 nm and that in the in-plane direction (a-axis) was 0.40853 nm, respectively. The lateral grain size (D) can be calculated as (integral width)−1 in the in-plane Bragg diffraction pattern. The RSMs of all films can be found in Figs. S2 and S3 in the supplementary material.

Figure 3 shows changes in κ of the undoped Ba1−xSr2SnO3 solid solution films as a function of x. At x = 0 (BaSnO3), κ is the highest (8 W m−1 K−1). This value monotonically decreases to ~2.8 W m−1 K−1 at x = 0.7. As x approaches 1, the κ increases to 4.4 W m−1 K−1. The κ of Ba1−xSr2SnO3 solid solution films exhibit a concavity and goes through a phase transition from the BaSnO3 dominated phase to the SrSnO3 dominated phase somewhere near x ~0.7. This type of behavior is commonly observed in phase transition systems due to the scattering from dopants, but κ of the Ba1−xSr2SnO3 system is a bit different from that of conventional solid solutions. In conventional material systems, heavier atoms usually suppress lattice vibrations and decrease κ.18 However, the κ of SrSnO3 (Sr = 87.62 amu) is lower than that of BaSnO3 (Ba = 137.33 amu). This suggests that the κ of Ba1−xSr2SnO3 solid solution films is dominated by a different factor.

Figure 4 summarizes the electron transport properties of 3% La-doped Ba1−xSr2SnO3 solid solution films as a function of x. The μH initially decreases from x = 0 (59 cm2 V−1 s−1) to x = 0.2 (29 cm2 V−1 s−1) and plateaus until x = 0.4 [Fig. 4(b)]. Then, the
\( \mu_{\text{Hall}} \) suddenly drops at \( x = 0.5 \) (12 cm\(^2\) V\(^{-1}\) s\(^{-1}\)) and slowly decreases until \( x = 0.8 \) (6 cm\(^2\) V\(^{-1}\) s\(^{-1}\)). As \( x \) approaches from 0.8 to 1, the \( \mu_{\text{Hall}} \) slowly increases up to 18 cm\(^2\) V\(^{-1}\) s\(^{-1}\). The other electrical transport properties (\( \sigma \), \( n \)) exhibit similar behaviors [Figs. 4(a) and 4(c)], and the magnitude of the thermopower (\( S \)) increases with decreasing \( n \) [Fig. 4(c)]. While the \( A \)-site substitution increases dopant scatterings, the changes observed in the electron transport properties are too versatile to be explained by the dopant scattering alone. The electron transport properties were not proportional to the lateral grain sizes \( D \) [Fig. 4 and Fig. S4(b) in the supplementary material]. This suggests that the carrier electron mobilities are not limited by the grain boundaries. Similar to thermal conductivity, this suggests that the electron transport properties of La-doped Ba\(_{1-x}\)Sr\(_x\)SnO\(_3\) solid solution films are controlled by a different factor.

Since BaSnO\(_3\) and SrSnO\(_3\) have different crystal structures, identifying changes in the lattice parameters is also crucial. Figure 5 shows the lattice parameters of the undoped and La-doped Ba\(_{1-x}\)Sr\(_x\)SnO\(_3\) solid solution films. The dotted lines in Figs. 5(a) and 5(c) are linear regressions from the lattice parameter of BaSnO\(_3\) (0.4116 nm) to that of SrSnO\(_3\) (0.4034 nm). The lattice...
parameter in the in-plane direction is defined as the \( a \)-axis and that in the out-of-plane direction is defined as the \( c \)-axis. Both the \( a \)-axis and \( c \)-axis lattice parameters of undoped BaSnO\(_3\) film are close to the bulk value, which indicates that the strain from the film/substrate interface is relaxed as we expected. Positive bowing is seen in the \( c \)-axis, whereas negative bowing is seen in the \( a \)-axis, showing that the \( a \)-axis is in compression while the \( c \)-axis is in tension. The lattice distortion is defined as \( \frac{c}{a} - 1 \) \( \times \) 100\%. The lattice distortion of the films maximizes at \( x = 0.7 - 0.8 \).

There are several possibilities of the origin of the lattice distortion. Since the lattice mismatch between the film and the substrate decreases with \( x \), the contribution of epitaxial strain would increase. However, the in-plane lattice parameter of the resultant films was always larger than that of the substrate. This shows that the epitaxial strain does not dominate the lattice distortion. In order to clarify the dominant origin of the lattice distortion, we performed the Rietveld analyses of the powder diffraction patterns of the Ba\(_{1-x}\)Sr\(_x\)SnO\(_3\) PLD target ceramics. We found that the space group of \( x \leq 0.5 \) is \( Pm\text{-}3m \) (cubic perovskite), whereas \( x \geq 0.7 \) is \( Pnma \) (orthorhombic perovskite) (Fig. S5 in the supplementary material). The crystal structures drawn from the Rietveld analysis results also demonstrate that the lattice distortion at \( x = 0.7 \) is much greater than that at \( x = 1 \) (Fig. S6 in the supplementary material). These results would indicate that the lattice distortion is spontaneously introduced due to the stability of orthorhombic symmetry around \( x \approx 0.7 \).

Interestingly, the changes observed in the lattice distortion are similar with those observed from the electron and thermal transport properties. In the undoped Ba\(_{1-x}\)Sr\(_x\)SnO\(_3\) solid solution system, BaSnO\(_3\) \( (x = 0) \) initially exhibits a near-perfect cubic structure, where the \( \kappa \) is the highest \( (8 \text{ W m}^{-1} \text{K}^{-1}) \). The lattice distortion gradually increases until \( x = 0.7 \), where the \( \kappa \) exhibits a minimum [Figs. 3 and 5(b)]. As \( x \) increases further, the lattice distortion gradually reduces until \( x = 1 \) (SrSnO\(_3\)). Since the bowing of lattice parameters occurred in the BaSnO\(_3\)–SrSnO\(_3\) solid solution system like the BaTiO\(_3\)–SrTiO\(_3\) system, the lattice distortion was maximized around \( x = 0.7 \), and the cubic structure is not fully recovered, which is consistent with the \( \kappa \) of SrSnO\(_3\) being lower than that of BaSnO\(_3\). However, unlike the lattice distortion, a plateau can be seen in \( \mu_{\text{Hall}} \) and \( n \) from \( x = 0.2 \) to 0.4. This plateau implies that the dopant scatterings from the \( A \)-site substitution are not significant but not trivial to understand. It seems that \( \sim 0.6\% \) is a critical distortion in SnO\(_3\) for the electron transport properties of ASnO\(_3\). For example, a sudden drop in \( \mu_{\text{Hall}} \) and \( n \) is observed at \( x = 0.5 \) when the lattice distortion reaches \( \sim 0.7\% \). In addition, an abrupt jump is observed in \( \mu_{\text{Hall}} \) and \( n \) at \( x = 0.9 \) when the lattice distortion reduces to \( \sim 0.5\% \). However, we would like to note that the lattice distortions from \( x = 0.2 \) to 0.4 are within the uncertainty \( (0.1\%) \), and the actual lattice distortion in this region may be similar. Compared to the undoped Ba\(_{1-x}\)Sr\(_x\)SnO\(_3\) solid solution films, which exhibited a transition at \( x = 0.7 \), the transition in the La-doped Ba\(_{1-x}\)Sr\(_x\)SnO\(_3\) solid solution films occurs a bit later \( (x = 0.8) \). This is likely attributed to the extra distortions in the La-doped Ba\(_{1-x}\)Sr\(_x\)SnO\(_3\) solid solutions from the La-dopants. In fact, the La-doped

![Figure 4](image-url)
Ba$_{1-x}$Sr$_x$SnO$_3$ solid solution films exhibit greater structural distortions compared to undoped Ba$_{1-x}$Sr$_x$SnO$_3$ solid solutions near $x = 0$ and $x = 1$ [Figs. 5(b) and 5(d)]. Since the propagation of vibrational waves is strongly affected by anharmonicity and strains in the lattice, the relationship between the lattice distortion and the $\kappa$ of Ba$_{1-x}$Sr$_x$SnO$_3$ system is not surprising. While the changes in the $\kappa$ of Ba$_{1-x}$Sr$_x$SnO$_3$ solid solution films are overall consistent with the changes observed from the lattice distortions [Fig. 2(c)], dopant scatterings also seem to play a minor role. For instance, the reduction of $\kappa$ from $x = 0$ to 0.2 is likely attributed to the dopant scattering since the lattice distortion in this region is not significant [Fig. 2(c)]. In other regions, the location of the lowest $\kappa$ and the highest lattice distortion ($x = 0.7$) suggests that the effect of lattice strain is stronger. Regarding the electron transport properties, the effect of lattice distortion demonstrates the relationship between anharmonicity and the electron scattering cross sections. However, the evolution of $n$ is not straightforward. Since the optical bandgap of SrSnO$_3$ ($\sim 4.6$ eV) is greater than that of BaSnO$_3$ ($\sim 3.2$ eV), reduction in the La-dopant activation with the substitution of Sr is expected, but the $n$ is not monotonic with the substitution of Sr. Figures 4(b) and 5(d) suggest that $n$ is also controlled by the lattice distortion. This can be related to the strain–defect coupling in oxides. The lattice distortion creates linear strains along the axis. This can promote the formation of defects that create defect levels and suppress the activation of dopants.\cite{23-28} These results demonstrate that the electron and thermal transport properties of perovskite ASnO$_3$ are dominated by the lattice distortion, and maintaining the symmetry of SnO$_6$ octahedron is the key for preserving their transport properties.

IV. SUMMARY

In summary, we investigated the effect of lattice distortion on the electron and thermal transport properties of Ba$_{1-x}$Sr$_x$SnO$_3$ solid solution films. The thermal conductivity of Ba$_{1-x}$Sr$_x$SnO$_3$ monotonically decreases from $x = 0$ to 0.7 and then again monotonically increases until $x = 1$. For $x \geq 0.2$, the changes in the thermal conductivity are attributed to the scatterings from Sr substitution. However, in other regions, the lattice distortion of SnO$_6$ octahedron played a greater role again. The electron transport properties exhibited a decreasing tendency from $x = 0$ to 0.8 and then increased until $x = 1$. The changes in the carrier concentrations and carrier electron mobility were highly consistent with the evolution of lattice distortions, whereas the scattering from A-site substitutions were not significant. Maintaining the symmetry of the SnO$_6$ octahedron was a crucial factor for obtaining high electron transport properties in this system. The results of this study clarify the importance of SnO$_6$ octahedron in the transport properties of ASnO$_3$, which will be valuable for unlocking their potential for device applications.
SUPPLEMENTARY MATERIAL

See the supplementary material for the topographic AFM images of the films, RSMs, lateral grain size, and Rietveld refinement results.
