Phospholipase A₂ isozyme II (PLA₂ II) which showed different mobility on native PAGE from that of the PLA₂ isozyme I (PLA₂ I) isolated previously was purified from pyloric ceca of the starfish (Asterina pectinifera). The PLA₂ II was mainly released oleic acid from 1-palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine. N-terminal amino acid sequence of the PLA₂ II was SVYQF. Temperature and pH optimums of the PLA₂ II were at around 50 °C and pH 9.0, respectively, and the enzyme activity was enhanced by sodium deoxycholate and 1 mM or higher concentration of Ca²⁺. The PLA₂ II did not show the fatty acid specificity for hydrolysis of phosphatidylcholine (PC). Specific activity of the PLA₂ II was about 10 times higher than that of commercially available porcine pancreatic PLA₂. The PLA₂ II hydrolyzed PC more effectively than phosphatidylethanolamine. These characteristics of the PLA₂ II were the same as those of the PLA₂ I.
INTRODUCTION

Phospholipase A$_2$ (PLA$_2$) (EC3.1.1.4) catalyzes the selective hydrolysis of the sn-2-acyl group in 1, 2-diacyl-sn-glycero-3-phospholipids. PLA$_2$ is widely distributed in tissues of various organisms and is classified into extracellular and intracellular types. Extracellular PLA$_2$ is abundant in mammalian pancreas and snake venom, and these enzymatic and structural characteristics have been well studied (Arni and Ward 1996; Dennis 1983).

On the other hand, the PLA$_2$s from mammalian pancreas and snake venom have been used as biochemical reagent. Stoll (1996) employed snake venom PLA$_2$ to analyze the positional distribution of fatty acids in glycerophospholipids from guinea pig and pig cardiac membranes. Mine (1997) examined structural and functional changes of hen egg-yolk low density lipoproteins (LDL) as a result of modifying its phospholipids using porcine pancreatic PLA$_2$. Additionally, commercial PLA$_2$ mainly produced from porcine pancreas is used for industrial processes in food industry. Soy lysophosphatidylcholine (lysoPC) which is an excellent emulsifier for food is prepared by porcine pancreatic PLA$_2$-catalyzed hydrolysis of soy phosphatidylcholine (PC) (Aoi, 1990). The emulsion with soy lysoPC is stable in various conditions at high temperature, acidic solution and high salt concentration. Soy lysoPC is also a good solubilizer, and the interaction between soy lysoPC and protein is very strong. Dahlke et al. (1995) reported that PLA$_2$ is suitable for the enzymatic degumming of edible oils. The enzymatic degumming of crude edible oils reduces the amounts of acids, bases, and wastes during the refining process. It also allows the extraction of PC and lysoPC as a valuable byproduct for the fortification of other foods. Recently, it was shown that LDL modified by PLA$_2$ was removed from the circulation to the liver more rapidly than unmodified LDL (Labeque et al. 1993). Based on this finding, a novel therapy for hypercholesterolemia has been recently developed that utilizes immobilized PLA$_2$ contained in an extracorporeal shunt.
In contrast, few studies exist on enzymology and application of PLA₂ from marine invertebrates. In the previous study, we isolated PLA₂ isozyme I (PLA₂ I) from the pyloric ceca of starfish (*Asterina pectinifera*), and showed its enzymatic properties comparing with those of mammalian pancreatic PLA₂ (Kishimura and Hayashi 1999b). The specific activity of the starfish PLA₂ I for PC was about 30 times higher than that of the commercially available PLA₂ from porcine pancreas (Sigma). In addition, the starfish PLA₂ I hydrolyzed PC more effectively than phosphatidylethanolamine (PE) like snake venom PLA₂, but not mammalian pancreatic PLA₂.

In this study, we purified PLA₂ isozyme II (PLA₂ II) from the pyloric ceca of starfish (*A. pectinifera*) and examined the characteristics of the PLA₂ II.

**MATERIALS AND METHODS**

Starfish (*A. pectinifera*) and squid (*Todarodes pacificus*) were caught off Sarufutsu and Hakodate, Hokkaido Prefecture, Japan, in April 2001 and September 2002, respectively. These specimens were stored at -20 °C for a few months. Porcine pancreatic PLA₂ were purchased from Sigma (St. Louis, MO, USA) and Amano Pharmaceutical Co. (Nagoya, Japan). Egg-yolk PC was purchased from Wako Pure Chemicals (Osaka, Japan). 1-palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine (POPC) was purchased from Avanti Polar Lipids, Inc. (Alabaster, AL, USA).

Crude enzyme solution was prepared by the same method as described by Kishimura and Hayashi (1999a). The crude enzyme solution was applied on a column (3.9×44 cm) of Sephacryl S-200 pre-equilibrated with 50 mM Tris-HCl buffer (pH8.0) and PLA₂ was eluted with the same buffer. Main active fraction was concentrated by lyophilization and dialyzed against 10 mM Tris-HCl buffer (pH8.0). The dialyzate was applied on a column (1.1×18 cm) of DEAE-cellulose
pre-equilibrated with 10 mM Tris-HCl buffer (pH8.0). PLA₂ was eluted with a linear gradient of NaCl from 0 to 0.5 M in 10 mM Tris-HCl buffer (pH8.0), and a main active fraction was obtained. The fraction was dialyzed against 10 mM Tris-HCl buffer (pH8.0) and the dialyzate was concentrated by lyophilization. The concentrate was applied on a column (3.9x64 cm) of Sephadex G-50 pre-equilibrated with 10 mM Tris-HCl buffer (pH8.0) and PLA₂ was eluted with the same buffer. Consequently, two active fractions were obtained. One of the two fractions was concentrated and re-chromatographed with Sephadex G-50. The final enzyme preparation (PLA₂ II) was found to be nearly homogeneous using SDS-PAGE (Fig. 1a) and native PAGE (Fig. 1b). The PLA₂ II was purified 52-fold from the crude enzyme solution in a yield of 7% (Table 1).

Extraction of tissue lipids and lipid analysis using thin-layer chromatography (TLC), preparative TLC, TLC-frame ionization detector method (TLC/FID), and gas-liquid chromatography (GLC) were performed as described by Hayashi (1989) and Hayashi and Kishimura (1996). PC and PE were prepared from the squid mantle muscle lipids, using preparative TLC with chloroform-methanol-acetic acid-water (55:17:3:2, v/v/v/v) as a developing solvent.

The PLA₂ activity was measured as described by Kishimura and Hayashi (1999b). One unit of enzyme activity was defined as the number of μg of the substrate hydrolyzed per min. Positional specificity and polar group specificity for PC and/or PE were analyzed by the method of Kishimura and Hayashi (1999b).

PAGE was carried out using a 12.5% polyacrylamide slab-gel with a Tris-HCl buffer at pH 8.9. SDS-PAGE was carried out using a 0.1% SDS-14% polyacrylamide slab-gel by the method of Laemmli (1970). The gel was stained with 0.1% Coomassie Brilliant Blue R-250 in 50% methanol-7% acetic acid and the background of the gel was destained with 7% acetic acid.

To analyze the N-terminal sequence of the purified PLA₂, the enzyme was electroblotted to polyvinylidenedifluoride (PVDF) membrane after SDS-PAGE. The amino acid sequence of the
enzyme was analyzed by using a protein sequencer, Procise 492 (Perkin Elmer, Foster City, CA, USA).

The protein concentration was determined by the method of Lowry et al. (1951) using bovine serum albumin as a standard.

RESULTS AND DISCUSSION

PLA$_2$ II which showed different mobility on native PAGE from the PLA$_2$ I previously isolated (Kishimura and Hayashi 1999b) was purified from the pyloric ceca of starfish *A. pectinifera*. Although the purified PLA$_2$ II showed the same molecular weight with PLA$_2$ I (about 20,000) on SDS-PAGE (Fig. 1a), the mobility of the starfish PLA$_2$ II on native PAGE was slightly greater than that of the starfish PLA$_2$ I (Fig. 1b). The positional specificity of the purified PLA$_2$ II was examined using POPC. The PLA$_2$ II released mainly oleic acid from POPC similar to the PLA$_2$ I and porcine pancreatic PLA$_2$ (Table 2).

The N-terminal amino acid sequence of the *A. pectinifera* PLA$_2$ II was determined after separation by SDS-PAGE and electroblotting to PVDF membrane. A sequence of five amino acid residues, SVYQF, was determined, indicating that the N-terminus of the PLA$_2$ II was unblocked. This sequence was completely consistent with that of the PLA$_2$ I (Kishimura et al. 2000). It was reported that the amino acid residues at positions 4 and 5 were Gln and Phe, respectively, in mammalian pancreatic PLA$_2$ and snake venom PLA$_2$ (Dennis 1983). These residues were conserved in the PLA$_2$ I and PLA$_2$ II.

The molecular weight of the *A. pectinifera* PLA$_2$ I and PLA$_2$ II was estimated as approximately 20,000 using SDS-PAGE, which was larger than those of mammalian pancreatic PLA$_2$ (about 14,000) (Fleer et al. 1991), red sea bream (*Pagrus major*) pyloric ceca PLA$_2$ (14,000)
(Iijima et al. 1997), and starfish (Solaster paxillatus) pyloric ceca PLA$_2$ (about 13,000) (Kishimura and Hayashi 1998). Mammalian pancreatic PLA$_2$ is secreted as a precursor and is activated by trypic hydrolysis (Verheij and De Haas 1991). Previously, we found that the crude enzyme solution prepared from fresh pyloric ceca of the starfish (A. pectinifera) showed a high phospholipase A activity (1,427 U/mg) similar to those from samples frozen at -20 °C for 35 or 46 months (1,214 and 1,655 U/mg, respectively) (Kishimura and Hayashi 1999a). Existence of the precursor of starfish PLA$_2$ was unknown.

Fig. 2 shows the pH and temperature dependences of the A. pectinifera PLA$_2$ II. The enzyme hydrolyzed egg-yolk PC substrate effectively at alkaline pH with an optimum activity of about pH 9.0, and it had an optimum temperature at about 50 °C. The pH dependence of the PLA$_2$ II was similar to those of starfish (A. pectinifera) pyloric ceca PLA$_2$ I (Kishimura and Hayashi 1999b), mammalian pancreatic PLA$_2$ (Arni and Ward 1996; Dennis 1983), red sea bream pyloric ceca PLA$_2$ (Iijima et al. 1997), and starfish (S. paxillatus) pyloric ceca PLA$_2$ (Kishimura and Hayashi 1998). Although the optimum temperature of the PLA$_2$ II was the same as starfish (A. pectinifera) pyloric ceca PLA$_2$ I (Kishimura and Hayashi 1999b), it was higher than that of starfish (S. paxillatus) pyloric ceca PLA$_2$ (about 30 °C) (Kishimura and Hayashi 1998).

The activity of the A. pectinifera PLA$_2$ II was enhanced by adding sodium deoxycholate at an optimum activity of 2 to 3 mM (Fig. 3). Fig. 4 shows the effect of CaCl$_2$ on the activity of PLA$_2$ II. The PLA$_2$ II was activated by 1 mM or higher concentration of Ca$^{2+}$. The activity of the PLA$_2$ II was stimulated most by adding Ca$^{2+}$ followed by Mg$^{2+}$ and Co$^{2+}$, while it was strongly inhibited by adding Hg$^{2+}$, Zn$^{2+}$, and EDTA (Table 3). These properties of the PLA$_2$ II was the same as those of the PLA$_2$ I (Kishimura and Hayashi 1999b), mammalian pancreatic PLA$_2$ (Arni and Ward 1996; Dennis 1983), and red sea bream pyloric ceca PLA$_2$ (Iijima et al. 1997).

The fatty acid specificity of the A. pectinifera PLA$_2$ II was examined using squid PC as a substrate. The compositions of fatty acids released from the substrate by the PLA$_2$ II were similar
to those released by the *A. pectinifera* PLA₂ I (Kishimura and Hayashi 1999b) and porcine pancreatic PLA₂ (Table 4). The PLA₂ I and PLA₂ II hydrolyzed the fatty acid ester bond exclusively at the glycerol-*sn*-2 position of PC regardless of chain length and degree of unsaturation, similar to mammalian pancreatic PLA₂ (Arni and Ward 1996; Dennis 1983) and starfish (*S. paxillatus*) pyloric ceca PLA₂ (Kishimura and Hayashi 1998).

The polar group specificity of the *A. pectinifera* PLA₂ II was examined using squid PC and PE. The PLA₂ II hydrolyzed PC more effectively than PE like the *A. pectinifera* PLA₂ I (Kishimura and Hayashi 1999b), but not porcine pancreatic PLA₂, which hydrolyzed PC almost equally to PE (Fig. 5). Mammalian pancreatic PLA₂ hydrolyzed PC almost equally to PE (De Haas *et al.* 1968), and snake venom PLA hydrolyzed PC more effectively than PE (Ibrahim *et al.* 1964). Also mammalian non-pancreatic extracellular PLA₂ hydrolyzed PE more effectively than PC (Hara *et al.* 1989). In this study, the PLA₂ II hydrolyzed PC more effectively than PE similar to the PLA₂ I (Kishimura and Hayashi 1999b) and snake venom PLA₂ (Ibrahim *et al.* 1964). Kuipers *et al.* (1989) reported that a recombinant porcine pancreatic PLA₂ mutant with a deletion of the pancreatic loop at positions 62-66 gave an intermediate conformation between wild type porcine PLA₂ and snake venom PLA₂, and enhanced the catalytic activity on zwitterionic substrates. Therefore, possibly the primary structures of PLA₂ I and PLA₂ II from the pyloric ceca of starfish (*A. pectinifera*) differed from that of mammalian pancreatic PLA₂ at the corresponding region to the pancreatic loop.

The specific activities of the *A. pectinifera* PLA₂ I and PLA₂ II for egg-yolk PC were 119,000 U/mg (Kishimura and Hayashi 1999b) and 52,000 U/mg, respectively. These activities were 27 times and 12 times higher, respectively, than that of the reagent grade PLA₂ from porcine pancreas (Sigma) (4,300 U/mg) measured using the same assay system.

In conclusion, the PLA₂ isozymes (PLA₂ I and PLA₂ II) from the pyloric ceca of starfish (*A. pectinifera*) hydrolyzed PC more effectively than PE unlikely porcine pancreatic PLA₂, which
hydrolyzed PC almost equally to PE. In addition, the specific activities of these isozymes for PC were 27 times (PLA$_2$ I) and 12 times (PLA$_2$ II) higher, respectively, than that of commercially available PLA$_2$ from porcine pancreas (Sigma). These results suggest that the pyloric ceca of the starfish (*A. pectinifera*) would be a potential source of PLA$_2$.

The graph shows the activity (U/ml) of an enzyme in response to varying concentrations of CaCl₂ (mM). The activity increases with increasing CaCl₂ concentration. There are two distinct curves, one represented by filled circles and the other by open circles, indicating different conditions or samples tested.

The x-axis represents CaCl₂ concentration in mM, ranging from 0 to 10. The y-axis represents activity in units per milliliter (U/ml), ranging from 0 to 40 x 10³. The points on the graph suggest a linear relationship between CaCl₂ concentration and enzyme activity.
One unit (U) of activity was defined as one µg of phosphatidylcholines hydrolyzed per min. DEAE - diethylaminoethyl.
