## Abstract

Among many thermoelectric materials, oxide-based materials draw significant interest due to their environmental compatibility. In particular, layered cobaltite,  $\text{Na}_{0.75}\text{CoO}_2$ , shows a large thermoelectric power factor parallel to the layers. However, the thermal conductivity ( $\kappa$ ) is rather high ( $5\text{--}7 \text{ W m}^{-1} \text{ K}^{-1}$ ), and therefore, its thermoelectric figure of merit  $ZT$  is small ( $\sim 0.03$ ) at room temperature. Here we show that substituting  $\text{Na}^+$  ion with  $\text{Ba}^{2+}$  ion in  $\text{Na}_x\text{CoO}_2$  drastically reduces the  $\kappa$  while keeping the large power factor, resulting in a large enhancement in  $ZT$ . We fabricated epitaxial films of  $\text{Na}_{0.75}\text{CoO}_2$  by reactive solid-phase epitaxy method and performed ion-exchange treatment from  $\text{Na}^+$  to  $\text{Ba}^{2+}$  to synthesize  $\text{Ba}_{0.27}\text{CoO}_2$  films. The room temperature electrical conductivity ( $\sigma$ ), thermopower ( $S$ ), and power factor of the  $c$ -axis oriented  $\text{Ba}_{0.27}\text{CoO}_2$  films along the in-plane direction were  $2310 \text{ S cm}^{-1}$ ,  $+72 \mu\text{V K}^{-1}$ , and  $1.2 \text{ mW m}^{-1} \text{ K}^{-2}$ , respectively, while the  $\kappa$  along the in-plane, which was clarified by

measuring the  $\kappa$  of the  $c$ -axis inclined ( $55^\circ$ ) film, was  $3.3 \text{ W m}^{-1} \text{ K}^{-1}$ . This yields a  $ZT$  ( $= S^2 \cdot \sigma \cdot T \cdot \kappa^{-1}$ ) value along the in-plane as high as 0.11 at room temperature, which is the highest among the oxide thermoelectric materials except oxychalcogenide,  $(\text{BiO})(\text{CuSe})$ .

## Introduction

Thermoelectric devices convert a temperature difference into electric current and vice versa, from the Seebeck effect/Peltier effect.<sup>1, 2</sup> Since thermoelectric devices can convert wasted heat exhausted in our daily life into electricity, it has attracted increasing attention as a potential solution for the realization of affordable and clean energy in Sustainable Development Goals (SDGs).<sup>3, 4</sup> Previously, wasted heat from large-scale high-temperature environments, like factories, thermal power plants, and automobiles, has been targeted for the thermoelectric conversion. Therefore, thermoelectric materials exhibiting a large figure of merit ( $ZT$ ) at high-temperature (800–1000 K) have been developed proactively.<sup>5–8</sup> Nevertheless, thermoelectric conversion of small-scale exhausted heat from computers, stoves, sunlight, and our body is also important for the realization of SDGs. Thus, thermoelectric materials exhibiting a large  $ZT$  around room temperature are also required.

Further, thermoelectric materials must avoid the use of rare and toxic elements since economic and environmental viabilities are of great concern in future. Therefore, although layered bismuth telluride based thermoelectric materials exhibit large  $ZT$  ( $= S^2 \cdot \sigma \cdot T \cdot \kappa^{-1} = \sim 0.8$ <sup>1</sup>, where  $S$ ,  $\sigma$ ,  $T$ , and  $\kappa$  are the thermopower, electrical conductivity, absolute temperature, and thermal conductivity) values at room temperature, they lack the sustainability due to the existence of Te, which is rare and a toxic. In this regard, oxide-based thermoelectric materials offer an excellent alternative due to their environmental compatibility.<sup>9</sup> Although it is known that oxychalcogenide  $(\text{BiO})(\text{CuSe})$ <sup>10, 11</sup> exhibits a large  $ZT \sim 0.2$  at room temperature and  $\sim 1.4$  at  $650^\circ\text{C}$ , chemical instability under oxygen atmosphere at high temperature can potentially cause problems in real application. One of the most commonly addressed thermoelectric oxides, electron-doped  $\text{SrTiO}_3$  and  $\text{Ca}_3\text{Co}_4\text{O}_9$ , exhibit large  $ZT$  values at elevated temperatures ( $ZT \sim 0.3$  at  $1000\text{ K}$  as the reliable value).<sup>12, 13</sup> However, the  $ZT$  values of these oxides are extremely small at room temperature ( $ZT \sim 0.05$  for electron doped  $\text{SrTiO}_3$ ,  $ZT \sim 0.04$  for  $\text{Ca}_3\text{Co}_4\text{O}_9$ ).<sup>12</sup> The origin of such low  $ZT$  observed from oxides at room temperature is their high  $\kappa$ . For example,  $\text{Na}_{0.75}\text{CoO}_2$  shows a large thermoelectric power factor ( $\text{PF} = S^2 \cdot \sigma$ ,  $2.38 \text{ mW m}^{-1} \text{ K}^{-2}$ ) along to the layers.<sup>14</sup> However, the  $\kappa$  is

rather high ( $\sim 7 \text{ W m}^{-1} \text{ K}^{-1}$ ), and therefore, the thermoelectric figure of merit  $ZT$  is small ( $\sim 0.03^{15, 16}$ ) at room temperature.

In order to overcome this difficulty, we recently investigated the effect of the ion exchange from  $\text{Na}^+$  ion to alkali earth ions on the  $\kappa$  of  $\text{Na}_{0.75}\text{CoO}_2$ .<sup>17</sup> Firstly, we fabricated  $\text{Na}_{0.75}\text{CoO}_2$  epitaxial films by the reactive solid-phase (R-SPE) epitaxy method.<sup>18-20</sup> Then, the  $\text{Na}^+$  ions were topotactically substituted with  $\text{Ca}^{2+}$  and  $\text{Sr}^{2+}$  ions by the conventional ion exchange treatment.<sup>21-23</sup> We measured the  $\kappa$  of the resultant epitaxial films of  $\text{Na}_{0.75}\text{CoO}_2$ ,  $\text{Ca}_{1/3}\text{CoO}_2$ , and  $\text{Sr}_{1/3}\text{CoO}_2$  using time-domain thermoreflectance (TDTR) method, and the result showed that the  $\kappa$  parallel to this layered structure can be reduced by substituting heavier elements between the  $\text{CoO}_2$  planes, as schematically hypothesized in Fig. 1, whereas the  $\kappa$  normal to the layered structure was  $\sim 1.5 \text{ W m}^{-1} \text{ K}^{-1}$ , independent on the element mass.<sup>17</sup>

In this study, we focused on the substitution of  $\text{Ba}^{2+}$  because the atomic mass of Ba is the heaviest among alkali earth elements. The thermoelectric properties of  $\text{Ba}_{1/3}\text{CoO}_2$  was addressed in few previous studies. Recently, Liu *et al.* fabricated  $\text{Ba}_x\text{CoO}_2$  ( $x = 0.19, 0.28, 0.30$ , and  $0.33$ ) ceramic samples through the ion-exchange treatment of

$\text{Na}_x\text{CoO}_2$  ceramics and measured the thermoelectric properties.<sup>24, 25</sup> They showed that the resistivity ( $\rho$ ),  $S$ , and  $\kappa$  of the  $\text{Ba}_x\text{CoO}_2$  ceramics at room temperature were  $4\text{--}30 \text{ m}\Omega \text{ cm}$  ( $\sigma = 33\text{--}250 \text{ S cm}^{-1}$ ),  $\sim 70 \text{ }\mu\text{V K}^{-1}$ , and  $3\text{--}5 \text{ W m}^{-1} \text{ K}^{-1}$ , respectively. Thus, the  $ZT$  of the  $\text{Ba}_x\text{CoO}_2$  ceramics at room temperature was 0.012 at the largest. The PF was 0.12  $\text{mW m}^{-1} \text{ K}^{-2}$ , which is an order magnitude lower than that of the epitaxial films of  $\text{Na}_{0.75}\text{CoO}_2$  ( $1.23 \text{ mW m}^{-1} \text{ K}^{-2}$ ),  $\text{Ca}_{1/3}\text{CoO}_2$  ( $1.08 \text{ mW m}^{-1} \text{ K}^{-2}$ ), and  $\text{Sr}_{1/3}\text{CoO}_2$  ( $1.18 \text{ mW m}^{-1} \text{ K}^{-2}$ ), measured parallel to the layered structure,<sup>17</sup> which is probably due to carrier scattering at grain or domain boundaries. On the other hand, the lowest  $\kappa$  was  $3 \text{ W m}^{-1} \text{ K}^{-1}$ , which is lower than that of the epitaxial films of  $\text{Na}_{0.75}\text{CoO}_2$  ( $5.46 \text{ W m}^{-1} \text{ K}^{-1}$ ),  $\text{Ca}_{1/3}\text{CoO}_2$  ( $6.79 \text{ W m}^{-1} \text{ K}^{-1}$ ), and  $\text{Sr}_{1/3}\text{CoO}_2$  ( $4.51 \text{ W m}^{-1} \text{ K}^{-1}$ ) (parallel to the layered structure).<sup>17</sup> From these points of view, we expected that  $\text{Ba}_{1/3}\text{CoO}_2$  epitaxial films show an enhanced  $ZT$  parallel to the layered structure as their power factor is not significantly damaged by grain or domain boundaries.

Here we report that the  $\text{Ba}_{1/3}\text{CoO}_2$  epitaxial films, which were fabricated by the ion exchange treatment of  $\text{Na}_{0.75}\text{CoO}_2$  epitaxial films exhibit significantly low  $\kappa$  while maintaining the large power factor and show rather large  $ZT = 0.11$  at room

temperature. This value is the highest among the oxide thermoelectric materials except oxychalcogenide,  $(\text{BiO})(\text{CuSe})$ .

## Experimental

**Preparation of  $\text{Na}_{0.75}\text{CoO}_2$  epitaxial films.** We prepared  $\text{Ba}_{1/3}\text{CoO}_2$  epitaxial films as schematically summarized in Fig. 2, which also shows the crystal structures of  $\text{CoO}$ ,  $\text{Na}_{0.75}\text{CoO}_2$ , and  $\text{Ba}_{1/3}\text{CoO}_2$ .  $\text{Na}_{0.75}\text{CoO}_2$  epitaxial films were prepared on  $\alpha\text{-Al}_2\text{O}_3$  substrates by the reactive solid-phase epitaxy (R-SPE) method.<sup>18-20</sup> First,  $\text{CoO}$  films were heteroepitaxially grown on (0001) or (1-100)  $\alpha\text{-Al}_2\text{O}_3$  single-crystal substrates (10 mm × 10 mm × 0.5 mm) at 700 °C in an oxygen atmosphere ( $10^{-3}$  Pa) by pulsed laser deposition technique (KrF excimer laser,  $\sim 2 \text{ J cm}^{-2}$  pulse<sup>-1</sup>, 10 Hz). Then, the surface of the  $\text{CoO}$  film was heated at 750 °C in air with  $\text{NaHCO}_3$  powder. In order to keep the film surface clean, the yttria stabilized zirconia (YSZ) single crystal plate (10 mm × 10 mm × 0.5 mm) was put on the film surface during the heating. Detailed preparation process of  $\text{Na}_{0.75}\text{CoO}_2$  epitaxial films is described elsewhere.<sup>18-20</sup>

**Ion exchange from  $\text{Na}^+$  to  $\text{Ba}^{2+}$ .** The ion exchange from  $\text{Na}^+$  to  $\text{Ba}^{2+}$  was performed by heating the  $\text{Na}_{0.75}\text{CoO}_2$  epitaxial films with molten  $\text{Ba}(\text{NO}_3)_2$  and  $\text{KNO}_3$  at 500 °C in an

alumina crucible for 1 h. After the ion exchange treatment, the resultant films were washed with distilled water. These processes were similar to the process used to prepare  $\text{Sr}_{1/3}\text{CoO}_2$  and  $\text{Ca}_{1/3}\text{CoO}_2$  epitaxial films by the ion exchange of  $\text{Na}_{0.75}\text{CoO}_2$  epitaxial films.<sup>22,23</sup>

**Crystallographic characterization of the films.** The crystallographic characteristics including the thickness, orientation, and lattice parameters of the resultant films were analyzed using the high-resolution X-ray diffraction (HR-XRD, Cu K $\alpha_1$  radiation, ATX-G, Rigaku Co.). Out-of-plane Bragg diffraction patterns, in-plane Bragg diffraction patterns, rocking curves, and X-ray reflection patterns were acquired. The surface morphologies of the resultant films were observed by a scanning probe microscopy (SPM, Nanocute, Hitach High-Tech Sci. Co.). Topographic atomic force microscope (AFM) images ( $2 \mu\text{m} \times 2 \mu\text{m}$ ) were acquired. The atomic arrangement of the resultant films was visualized using high-angle annular dark-field scanning transmission electron microscopy (HAADF-STEM).

**Measurements of the electrical conductivity and thermopower.** The electrical conductivity of the resultant films was measured by dc four-probe method in van der

Pauw electrode configuration. The thermopower of the resultant films was measured by the conventional steady-state method. The film sample was placed on the gap (~5 mm) between two Peltier devices. By applying the forward/reverse current to each Peltier device, temperature differences were generated in the sample. We then measured the temperature difference ( $\Delta T$ ) and the thermo-electromotive force ( $\Delta V$ ) simultaneously at room temperature, and the thermopower was calculated as the linear slope of the  $\Delta T - \Delta V$  plot (Supplementary Fig. S1). Details of our thermopower measurement system are described elsewhere.<sup>26, 27</sup>

**Measurements of the thermal conductivity.** Cross-plane thermal conductivity ( $\kappa$ ) of the resultant films was measured by the time domain thermo-reflectance (TDTR, PicoTR, PicoTherm Co.). 116-nm-thick Mo was deposited on the resultant films as a transducer by dc sputtering. The decay curves of the TDTR signals were simulated using the packaged software developed by PicoTherm Co. In our simulation, to minimize the number of free parameters, we used constant values for Mo transducers, including bulk density =  $10000 \text{ kg m}^{-3}$ , heat capacity ( $C_p$ ) =  $250 \text{ J Kg}^{-1} \text{ K}^{-1}$  and  $\kappa = 45.4 \text{ W m}^{-1} \text{ K}^{-1}$ . Details of our thermal conductivity measurement system are described elsewhere.<sup>17, 28, 29</sup>

**Uncertainty in the  $ZT$  value.** We fabricated more than 5 samples and we measured all samples. The uncertainty in the  $S$  and the  $\sigma$  were less than 5%, while that in the  $\kappa$  was ~15%. Therefore, the uncertainty in the  $ZT$  is approximated to be ~20%.

## Results and discussion

Figure 3 summarizes the out-of-plane XRD patterns and the topographic atomic force microscope (AFM) images of the resultant CoO film (Figs. 3a and 3d), R-SPE grown  $\text{Na}_{0.75}\text{CoO}_2$  film (Figs. 3b and 3e), and  $\text{Ba}^{2+}$  ion-exchanged film (Figs. 3c and 3f) grown on (0001)  $\alpha\text{-Al}_2\text{O}_3$  substrates. Only an intense Bragg peak of 111 CoO is seen together with 0006  $\alpha\text{-Al}_2\text{O}_3$  substrate (Fig. 3a), indicating the strong (111) orientation in the CoO film. The full width at half maximum (FWHM) of the out-of-plane rocking curve (OXRC) of 111 CoO was ~0.02° (Supplementary Fig. S2a), which is almost as small as the resolution of our optical setup of the XRD. The thickness of the CoO film was 93 nm, which was evaluated using the Pendellösung fringes around the Bragg peak of 111 CoO. The heteroepitaxial growth with the relationship of (111)[1-10] CoO || (0001)[1-100]  $\alpha\text{-Al}_2\text{O}_3$  was confirmed by the in-plane XRD patterns (Supplementary Fig. S3a).

Triangle shaped facets are clearly seen in the topographic AFM image of the film (Fig. 3d), confirming the heteroepitaxial growth of CoO.

After the R-SPE treatment, only intense Bragg peaks of  $000l$   $\text{Na}_{0.75}\text{CoO}_2$  are seen (Fig. 3b). The thickness of the  $\text{Na}_{0.75}\text{CoO}_2$  film was 182 nm, roughly twice that of the CoO film. Although the FWHM of the OXRC of  $0002$   $\text{Na}_{0.75}\text{CoO}_2$  was  $\sim 0.6^\circ$  (Supplementary Fig. S2b), hexagonal-shaped plate-like crystals with large terrace was observed in the topographic AFM image (Fig. 3e). Thus, the broadening of the FWHM of the OXRC indicates the bending of the  $\text{Na}_{0.75}\text{CoO}_2$  crystal. The in-plane XRD pattern (Supplementary Fig. S3b) confirmed the heteroepitaxial growth of  $\text{Na}_{0.75}\text{CoO}_2$  film on  $(0001)$   $\alpha\text{-Al}_2\text{O}_3$  substrate with the epitaxial relationship of  $(0001)[11\bar{2}0]\text{Na}_{0.75}\text{CoO}_2 \parallel (0001)[1\bar{1}00]\alpha\text{-Al}_2\text{O}_3$ . After the  $\text{Ba}^{2+}$  ion exchange treatment, the Bragg peak position of  $000l$  is shifted to the left, indicating a lattice expansion in the out-of-plane direction (Fig. 3c). The  $c$ -axis lattice parameter is  $12.225$  Å, which corresponds well with the reported value ( $12.2$  Å<sup>25</sup>) of  $\text{Ba}_{1/3}\text{CoO}_2$ . The in-plane XRD pattern (Supplementary Fig. S3c) indicated that there are two ordering structures of Ba ions. The  $a$ -axis lattice parameter was calculated to be  $2.829$  Å. The topographic AFM image of the resultant film (Fig. 3f) is similar to that of the  $\text{Na}_{0.75}\text{CoO}_2$  film.

Since the orientation of the films was inclined on (1-100)  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> substrate, Bragg diffraction peaks were not observed in the out-of-plane Bragg patterns of the resultant CoO film, R-SPE grown Na<sub>0.75</sub>CoO<sub>2</sub> film, and Ba<sup>2+</sup> ion-exchanged film (data not shown). Figures 3g–3i show the topographic AFM images of the CoO (Fig. 3g), Na<sub>0.75</sub>CoO<sub>2</sub> (Fig. 3h), and Ba<sup>2+</sup> ion-exchanged (Fig. 3i) films grown on (1-100)  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> substrate by the same way. Stripe patterns were seen in Figs. 3g–3i, which are similar to the surface of inclined films. The heteroepitaxial growth of CoO, Na<sub>0.75</sub>CoO<sub>2</sub>, and Ba<sub>1/3</sub>CoO<sub>2</sub> films on (1-100)  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> substrate was confirmed by the in-plane XRD patterns (Supplementary Fig. S4); [1-10] CoO || [0001]  $\alpha$ -Al<sub>2</sub>O<sub>3</sub>, [11-20] Na<sub>0.75</sub>CoO<sub>2</sub> || [0001]  $\alpha$ -Al<sub>2</sub>O<sub>3</sub>, and [11-20] Ba<sub>1/3</sub>CoO<sub>2</sub> || [0001]  $\alpha$ -Al<sub>2</sub>O<sub>3</sub>.

To further clarify the orientation of the film and the atomic arrangement, we performed high-angle annular dark-field scanning transmission electron microscopy (HAADF-STEM) observation. Figures 4a and 4b show the cross-sectional HAADF-STEM images of the Ba<sup>2+</sup> ion-exchanged films on (0001)  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> substrate. The e-beam incident direction is along the [1-100]  $\alpha$ -Al<sub>2</sub>O<sub>3</sub>. The layered atomic arrangement parallel to the substrate surface is clearly visualized (Fig. 4b and Supplementary Fig. S5a).

Approximately 10-nm-thick amorphous layer is also detected between the layered crystal and the substrate. Energy dispersive X-ray spectroscopy (EDS) results of the film (data not shown) revealed that the upper part of the film is composed of Ba, Co, and O. Signal from Na was negligible. The bottom amorphous part is composed of Ba, Al, and O. The concentration ratio of Ba/Co inside the film was about 0.27. These results show that the resultant film is  $\text{Ba}_{0.27}\text{CoO}_2$ .

On the other hand, an inclined layered structure was revealed in the HAADF-STEM images of the film on (1-100)  $\alpha\text{-Al}_2\text{O}_3$  substrate (Figs. 4c and 4d). The e-beam incident direction is along with the [0001]  $\alpha\text{-Al}_2\text{O}_3$ . Similar to the  $\text{Ba}_{0.27}\text{CoO}_2$  film on (0001)  $\alpha\text{-Al}_2\text{O}_3$  substrate, the layered atomic arrangement is clearly visualized. It should be noted that the layer is inclined 55° to the substrate surface. Although the interface amorphous layer is thick (15–30 nm), the crystal structure and the chemical composition of the layered crystal layer is similar to those of the  $\text{Ba}_{1/3}\text{CoO}_2$  film on (0001)  $\alpha\text{-Al}_2\text{O}_3$  substrate. The inclined structure is consistent with the topographic AFM image (Fig. 3i).

Then, we measured the electrical conductivity ( $\sigma$ ) and thermopower ( $S$ ) parallel to the film surface of the (0001)-oriented  $\text{Ba}_{0.27}\text{CoO}_2$  film grown on (0001)  $\alpha\text{-Al}_2\text{O}_3$  substrate

at room temperature. The  $\sigma$  was  $2310 \text{ S cm}^{-1}$ , the  $S$  was  $+72 \mu\text{V K}^{-1}$ , and the power factor ( $\text{PF} = S^2 \cdot \sigma$ ) was  $1.2 \text{ mW m}^{-1} \text{ K}^{-2}$ , respectively. The PF is the same ( $1.2 \text{ mW m}^{-1} \text{ K}^{-2}$ ) with that of (0001)-oriented  $\text{Na}_{0.75}\text{CoO}_2$  film grown on (0001)  $\alpha\text{-Al}_2\text{O}_3$  substrate at room temperature. Thus, Ba ion substitution does not affect the PF.

Next, we measured the thermal conductivity ( $\kappa$ ) normal to the film surface of the  $\text{Ba}_{0.27}\text{CoO}_2$  films grown on (0001) and (1-100)  $\alpha\text{-Al}_2\text{O}_3$  substrates by the TDTR method at room temperature. The  $\kappa$  of the  $\text{Ba}_{0.27}\text{CoO}_2$  film on (0001)  $\alpha\text{-Al}_2\text{O}_3$  substrate was  $1.3 \text{ W m}^{-1} \text{ K}^{-1}$  and that on (1-100)  $\alpha\text{-Al}_2\text{O}_3$  substrate was  $2.8 \text{ W m}^{-1} \text{ K}^{-1}$ . In order to extract the  $\kappa$  of the parallel to the layered structure in  $\text{Ba}_{0.27}\text{CoO}_2$  film, we used following equation as reported previously.<sup>17</sup>

$$\kappa_{\text{obsd}} = \sqrt{\kappa_{\parallel}^2 \cos^2 \varphi + \kappa_{\perp}^2 \sin^2 \varphi}$$

where  $\varphi$ ,  $\kappa_{\text{obsd}}$ ,  $\kappa_{\parallel}$  and  $\kappa_{\perp}$  are the inclined angle of the layers to perpendicular of the film surface, the observed thermal conductivity, thermal conductivity parallel and perpendicular to the  $\text{CoO}_2$  layers, respectively. Note that isotropy is recovered if  $\kappa_{\parallel} = \kappa_{\perp}$ , and this equation can be applied both isotropic and anisotropic materials.<sup>26</sup> In the case of this study,  $\varphi = 90 - 55 = 35^\circ$ ,  $\kappa_{\perp} = 1.3 \text{ W m}^{-1} \text{ K}^{-1}$  and  $\kappa_{\text{obsd}} = 2.8 \text{ W m}^{-1} \text{ K}^{-1}$ , the

$\kappa_{//}$  was calculated to be  $3.29 \text{ W m}^{-1} \text{ K}^{-1}$  (Supplementary Fig. S6), which is  $\sim 60\%$  of that of  $\text{Na}_{0.75}\text{CoO}_2$  epitaxial film as hypothesized.

Here we summarize and compare the thermoelectric properties of the  $\text{Ba}_{0.27}\text{CoO}_2$  and  $\text{Na}_{0.75}\text{CoO}_2$  films on (0001)  $\alpha$ - $\text{Al}_2\text{O}_3$  substrate along with reported values for  $\text{Ca}_{1/3}\text{CoO}_2$  and  $\text{Sr}_{1/3}\text{CoO}_2$ <sup>22, 23</sup> (Fig. 5 and Supplementary Table S1). Although there are some differences in the in-plane electrical conductivity ( $\sigma_{\text{ip}}$ ) (Fig. 5a) and thermopower ( $S_{\text{ip}}$ ) (Fig. 5b) of  $\text{Ca}_{1/3}\text{CoO}_2$ ,  $\text{Na}_{0.75}\text{CoO}_2$ ,  $\text{Sr}_{1/3}\text{CoO}_2$  and  $\text{Ba}_{0.27}\text{CoO}_2$ , the power factor  $\text{PF}_{\text{ip}}$  (Fig. 5c) was almost constant ( $1.08\text{--}1.2 \text{ mW m}^{-1} \text{ K}^{-2}$ ) and does not show clear dependence on the atomic mass of  $A_x$ . The main difference was detected in the thermal conductivity ( $\kappa$ ) (Fig. 5d). Although the out-of-plane thermal conductivity ( $\kappa_{\text{op}}$ ) was almost independent on the atomic mass of  $A_x$ , the  $\kappa_{\text{ip}}$  drastically decreased from  $6.79 \text{ W m}^{-1} \text{ K}^{-1}$  to  $3.29 \text{ W m}^{-1} \text{ K}^{-1}$  with increasing the atomic mass of  $A_x$  from  $13.2$  ( $\text{Ca}_{1/3}$ ) to  $45.3$  ( $\text{Ba}_{1/3}$ ), resulting in a significant enhancement in  $ZT$  along with the layered structure. The resulting  $ZT_{\text{in}}$  was  $0.11$  at room temperature, which is the highest among the oxide thermoelectric materials except oxychalcogenide,  $(\text{BiO})(\text{CuSe})$ .

## **Conclusions**

In summary, we have shown that  $\text{Ba}^{2+}$  ion substitution with  $\text{Na}^+$  ion in  $\text{Na}_{0.75}\text{CoO}_2$  significantly reduces the in-plane  $\kappa$  while keeping the large power factor, resulting in the large enhancement of  $ZT$ . We fabricated the epitaxial films of  $\text{Ba}_{1/3}\text{CoO}_2$  from  $\text{Na}_{0.75}\text{CoO}_2$  epitaxial films by ion-exchanging  $\text{Na}^+$  and  $\text{Ba}^{2+}$ . The  $\sigma$ ,  $S$ , and power factor of the  $c$ -axis oriented  $\text{Ba}_{1/3}\text{CoO}_2$  films along the in-plane were  $2310 \text{ S cm}^{-1}$ ,  $+72 \mu\text{V K}^{-1}$ , and  $1.2 \text{ mW m}^{-1} \text{ K}^{-2}$ , respectively. The  $\kappa$  along the in-plane, which was clarified by measuring the  $\kappa$  of the  $c$ -axis inclined ( $55^\circ$ ) film, was  $3.29 \text{ W m}^{-1} \text{ K}^{-1}$ . The  $ZT$  along the in-plane was as large as 0.11 at room temperature, which is the highest among the oxide thermoelectric materials except oxychalcogenide,  $(\text{BiO})(\text{CuSe})$ .

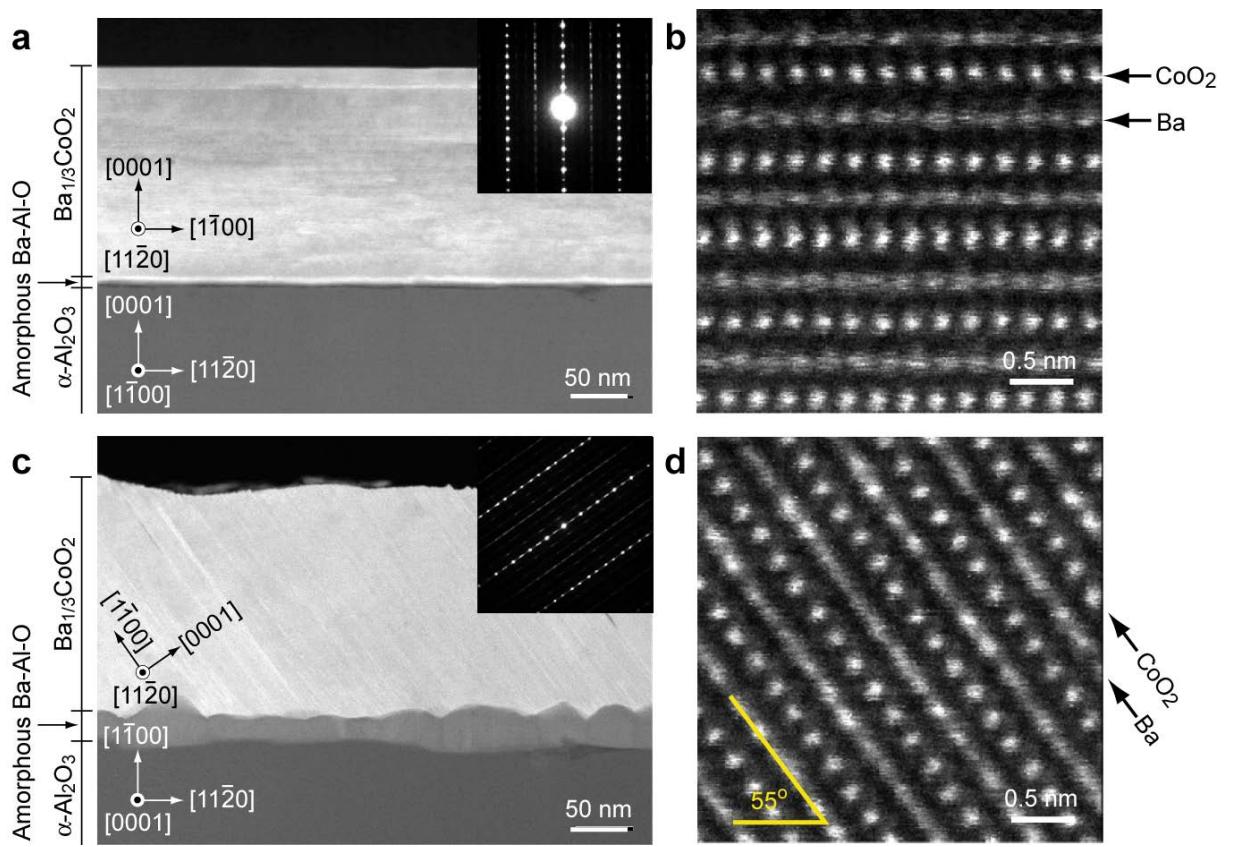

**Figure 1.** Hypothesis toward the  $ZT$  improvement of layered cobaltite,  $A_xCoO_2$ . We expected that the lattice vibration, indicated by red arrows of the rigid  $CoO_2$  layer would be significantly suppressed by the substitution of  $A$  ion from (a) light one to (b) heavy one. If the substitution does not affect the power factor ( $S^2 \cdot \sigma$ ), the  $ZT$  would be improved significantly by the substitution.

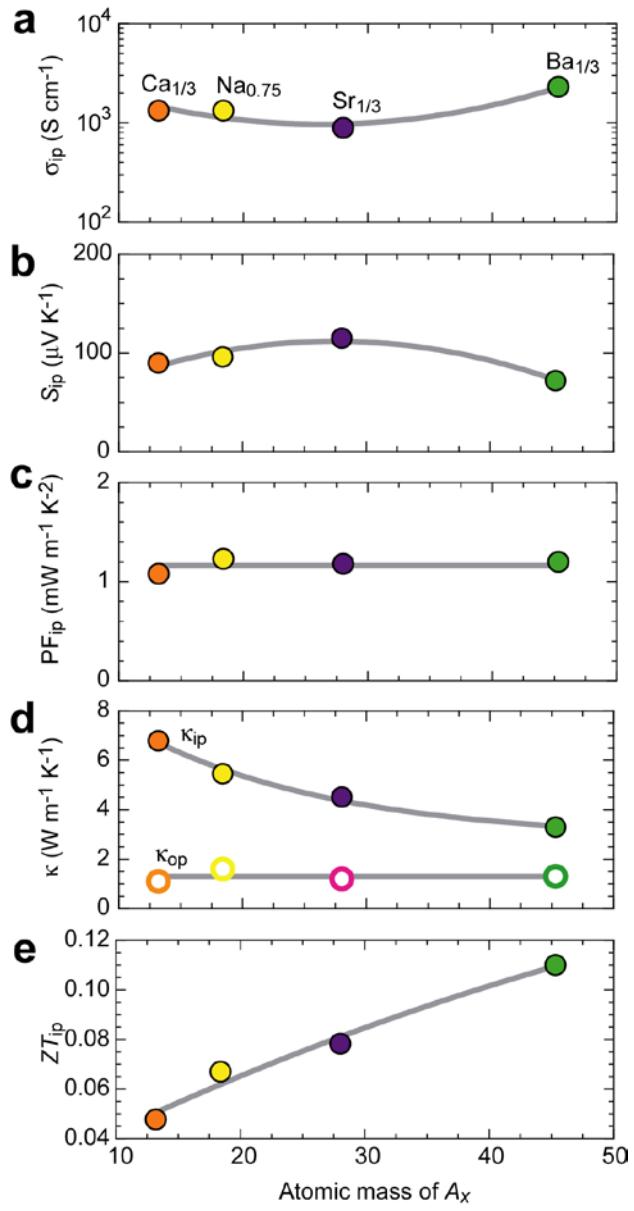

**Figure 2.** Fabrication procedure of Ba<sub>1/3</sub>CoO<sub>2</sub> epitaxial films. Step 1: CoO epitaxial film growth by the pulsed laser deposition on  $\alpha\text{-Al}_2\text{O}_3$  substrates. Step 2: Na<sub>0.75</sub>CoO<sub>2</sub> film growth by the Reactive Solid-Phase Epitaxy method. Step 3: Ion exchange treatment from Na to Ba. After the ion exchange treatment, the resultant film was washed by distilled water several times.

**Figure 3.** Crystal structural analyses of the resultant films. (a)–(c) Change in the out-of-plane XRD pattern of the resultant films grown on (0001)  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> substrate (a) after step 1, (b) after step 2, and (c) after step 3. The crystalline phase of (a) is CoO (93 nm), (b) is Na<sub>0.75</sub>CoO<sub>2</sub> (182 nm), and (c) is Ba<sub>1/3</sub>CoO<sub>2</sub> (200 nm). (d)–(f) Topographic AFM images of the resultant films grown on (0001)  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> substrate (a) after step 1 (CoO), (b) after step 2 (Na<sub>0.75</sub>CoO<sub>2</sub>), and (c) after step 3 (Ba<sub>1/3</sub>CoO<sub>2</sub>). (g)–(i) Topographic AFM images of the resultant films grown on (1-100)  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> substrate (a) after step 1, (b) after step 2, and (c) after step 3. All the scale bars are 1  $\mu\text{m}$ . Plate-like grains are seen in (d)–(f), whereas stripe patterns are seen in (g)–(i).

**Figure 4.** Cross-sectional atomic arrangement of the  $\text{Ba}_{1/3}\text{CoO}_2$  films. (a) Cross-sectional HAADF-STEM image of the  $\text{Ba}_{1/3}\text{CoO}_2$  epitaxial film grown on (0001)  $\alpha\text{-Al}_2\text{O}_3$  substrate. The selected area electron diffraction pattern and (b) the magnified HAADF-STEM image reveals that Ba and  $\text{CoO}_2$  layers are stacked parallel to the substrate surface. (c) Cross-sectional HAADF-STEM image of the  $\text{Ba}_{1/3}\text{CoO}_2$  epitaxial film grown on (1-100)  $\alpha\text{-Al}_2\text{O}_3$  substrate. The selected area electron diffraction pattern and (d) the magnified HAADF-STEM image reveals that Ba and  $\text{CoO}_2$  layers are inclined 55° to the substrate surface.

**Figure 5.** Thermoelectric properties of A<sub>x</sub>CoO<sub>2</sub> epitaxial films at room temperature. (a) in-plane electrical conductivity (σ<sub>ip</sub>), (b) in-plane thermopower (S<sub>ip</sub>), (c) in-plane power factor (PF<sub>ip</sub>), (d) in-plane and out-of-plane thermal conductivity (κ<sub>ip</sub>, κ<sub>op</sub>), and (e) in-plane figure of merit (ZT<sub>ip</sub>) as a function of the atomic mass of A<sub>x</sub> in A<sub>x</sub>CoO<sub>2</sub>. The κ<sub>ip</sub> shows a clear decreasing tendency whereas the PF shows a slightly increasing tendency. These resulted in an increasing tendency of ZT. The ZT reached 0.11 when A<sub>x</sub> = Ba<sub>1/3</sub>.
