Instantaneous number-average sequence length of monomers $\langle N_M \rangle$ in polymer chains at different conversion point

Based on the free radical polymerization theory,[1] during the chain growth reaction, the probability of adding an M_1 monomer unit to an M_1 end chain, denoted as p_{11}, at any conversion point p, can be expressed as:

$$p_{11}(p) = \frac{r_1 f_1(p)}{r_1 f_1(p) + f_2(p)} \tag{S1}$$

Where conversion point p is the total conversion of monomers, r_1 is monomer reactivity ratio for the addition of monomer M_1 and M_2 to the M_1 end chain. $f_1(p)$ and $f_2(p)$ are the molar fraction of monomers M_1 and M_2 at conversion p, respectively. Similarly, the probability of adding an M_2 monomer unit to an M_2 end chain, denoted as p_{22}, can be expressed,

$$p_{22}(p) = \frac{r_2 f_2(p)}{r_2 f_2(p) + f_1(p)} \tag{S2}$$

Where r_2 is monomer reactivity ratio for the addition of monomers M_2 and M_1 to the M_2 end chain. The probabilities $(p_{M_1})_x$ and $(p_{M_2})_x$ of forming M_1 and M_2 sequences of length x are given by

$$(p_{M_1})_x = p_{11}^{x-1}(1 - p_{11}) \tag{S3}$$

$$(p_{M_2})_x = p_{22}^{x-1}(1 - p_{22}) \tag{S4}$$

The value of $(p_{M_1})_x$ and $(p_{M_2})_x$ at each point p is hence the instantaneous sequence length distribution. The instantaneous number-average sequence lengths of monomers M_1 and M_2 at conversion p, $\langle N_{M1} \rangle$ and $\langle N_{M2} \rangle$, respectively, are:

$$\langle N_{M_1} \rangle(p) = \frac{1}{1 - p_{11}(p)} \tag{S5}$$

$$\langle N_{M_2} \rangle(p) = \frac{1}{1 - p_{22}(p)} \tag{S6}$$

Therefore, the fraction of the number of M_1 in xM_1 segment to the total number of M_1 is

$$\phi_{M_1}(x) = \frac{x(p_{M_1})_x}{\sum x(p_{M_1})_x} = xp_{11}^{x-1}(1-p_{11})^2 \qquad (S7)$$

Similarly, the fraction of the number of M_2 in xM_2 segment to the total number of M_2 is

$$\phi_{M_2}(x) = \frac{x(p_{M_2})_x}{\sum x(p_{M_2})_x} = xp_{22}^{x-1}(1-p_{22})^2 \qquad (S8)$$

Calculation of percentage of monomer in adjacent location

Here we derived the equation for the percentage of monomer in adjacent sequence. For a segment with one M_1 sequence length ($x = 1$), all M_1 are adjacent to M_2, namely the percentage of M_1 in adjacent to M_2 is

$$(p_{M_1}{}^{adj})_1 = 100\% \qquad (S9)$$

When sequence length of M_1 is larger than 1 ($x = 2, 3...$), the percentage that M_1 is adjacent to M_2 for x sequence length is

$$(p_{M_1}{}^{adj})_x = \frac{2}{x} \times 100\% \qquad (S10)$$

Then the total percentage that M_1 is adjacent to M_2 in total number of M_1 is

$$P_{M_1}{}^{adj} = \phi_{M_1}(x = 1) \times (p_{M_1}{}^{adj})_1 + \sum_{x=2}^{n}[\phi_{M_1}(x) \times (p_{M_1}{}^{adj})_x] \qquad (S11)$$

Similarly, the total percentage that M_2 is adjacent to M_1 in total number of M_2 is

$$P_{M_2}{}^{adj} = \phi_{M_2}(x = 1) \times (p_{M_2}{}^{adj})_1 + \sum_{x=2}^{n}[\phi_{M_2}(x) \times (p_{M_2}{}^{adj})_x] \qquad (S12)$$

Based on the equation S11 and S12, the total percentage of M_1 and M_2 in adjacent location in polymer chains is

$$P_M{}^{adj} = \frac{[M_1]P_{M_1}{}^{adj} + [M_2]P_{M_2}{}^{adj}}{[M_1] + [M_2]} \tag{S13}$$

By using r_1, r_2 values in Table 1, and $f_1(p)$, $f_2(p)$ determined experimentally, we estimated conversion p dependence of $\langle N_{M1} \rangle$ and $\langle N_{M2} \rangle$ using Eqs. S5, S6 for equimolar ratio of ATAC-BZA pair and ATAC-PEA pair in different solvent, and the results are shown in Figure 2g and 2h. The percentage of adjacent sequence for equimolar ratio of ATAC-BZA pair and ATAC-PEA pair in DMSO were estimated from Equation S13 using r_1, r_2 values in Table 1.
