19 sequestration

20 **Abstract**

21 A 4-year-old boy with left intralobar pulmonary sequestration associated with left main  
22 coronary artery obstruction (LMCAO) and severe mitral regurgitation (MR) was admitted to  
23 our hospital. Since the patient presented with dyskinesia of the cardiac apex and increased  
24 left ventricular end-diastolic volume (LVEDV), left main coronary artery reconstruction and  
25 mitral annuloplasty were performed. The enlargement of the left ventricle was improved after  
26 sequential surgeries. There was a risk of deterioration of MR and regrowth of LVEDV due to  
27 shunt blood flow; therefore, left lower lobectomy and aberrant artery division were  
28 performed. This is a very rare case of a patient with pulmonary sequestration associated with  
29 LMCAO and severe MR.

38

39 **Introduction**

40 Pulmonary sequestration accounts for approximately 5% of congenital lung diseases. The  
41 shunt volume due to aberrant arteries is usually mild; however, sometimes, there are cases of  
42 increased shunt volume causing left ventricular volume overload and symptoms of heart  
43 failure.<sup>1-6)</sup> Extralobar pulmonary sequestration is often associated with malformations of  
44 other organs; however, intralobar pulmonary sequestration is rare. Herein, we report the case  
45 of a patient with left main coronary artery obstruction (LMCAO), severe mitral regurgitation  
46 (MR), and left intralobar pulmonary sequestration, who was successfully treated with  
47 sequential surgical treatment.

48

49 **Case**

50 A 4-year-old boy was diagnosed with acute pneumonia, and a dilated heart shadow was found  
51 on X-ray. Physical examination revealed Levine II/VI systolic murmurs. Laboratory  
52 investigations showed a high brain natriuretic peptide (BNP) level (96.5 pg/mL). Computed  
53 tomography (CT) showed an overinflated area and multicystic changes in the left lower lobe  
54 of the lungs (Figure 1a). Three-dimensional CT and cardiac catheterization showed an  
55 aberrant artery arising from the descending aorta (Figures 1b and c). Blood from the  
56 sequestration returned to the left atrium via the left inferior pulmonary vein (Figures 1b and  
57 d). No connection between the normal bronchus and the sequestered lungs was observed.

58 Therefore, the patient was diagnosed with intralobar pulmonary sequestration. Transthoracic  
59 echocardiography (TTE) showed dyskinesia of the cardiac apex and severe MR. Cardiac  
60 catheterization revealed systemic blood flow, pulmonary artery wedge pressure, left ventricle  
61 pressure, end-diastolic pressure, left ventricular end-diastolic volume (LVEDV), and left  
62 ventricular ejection fraction of 4.2 mL/min, 14 mmHg, 101 mmHg, 9 mmHg, 306% of  
63 normal, and 44%, respectively. Moreover, a grade III MR was revealed. Coronary  
64 angiography (CAG) showed 99% occlusion of the left coronary artery and severe stenosis of  
65 the main trunk, and it was diagnosed as LMCAO (Figure 2a). The anterior descending and  
66 circumflex branches were imaged in a retrograde manner through the collateral route from  
67 the right coronary artery. The undeveloped coronary arteries from the apex to the lateral wall  
68 were also imaged (Figure 2b).

69 Left main coronary artery reconstruction and semicircular mitral annuloplasty were  
70 performed for LMCAO, left ventricular dysfunction, and MR (Figure 3). The intraoperative  
71 findings confirmed that blood flow from the left inferior pulmonary vein was abundant. Left  
72 main trunk (LMT) incision was performed, an inverted U-shaped incision was made in the  
73 left sinus of Valsalva, a flap was anastomosed to the anterior wall of the LMT, and the  
74 remaining anterior LMT plasty was performed with a 12 × 8 mm trapezoidal main pulmonary  
75 artery wall patch. The intraoperative findings showed a prolapse in the A2 and A3 of the  
76 mitral valve. The posterior leaflet was extended throughout. Semicircular mitral annuloplasty

77 was performed according to the size of the anterior leaflet. The defect of the main pulmonary  
78 artery was repaired with autologous pericardium. The patient left the intensive care unit the  
79 day after surgery and was discharged from the hospital on the eleventh postoperative day.

80 There was a risk of deterioration of MR and regrowth of LVEDV due to excess shunt blood  
81 flow; therefore, early surgical intervention for pulmonary sequestration was scheduled.

82 Thoracoscopic left lower lobectomy and aberrant artery division were performed 65 days  
83 after the heart surgery. The intraoperative findings confirmed an abnormal blood vessel  
84 branching from the descending aorta and draining via the inferior pulmonary vein. The  
85 patient successfully recovered and was discharged from the hospital on the sixth  
86 postoperative day. Written informed consent was obtained from this patient's parents during  
87 both surgeries.

88 TTE 2 days and 10 months after left lower lobectomy and aberrant artery division suggested  
89 that the remaining moderate MR was probably due to papillary muscle dysfunction. A  
90 remarkable regression of the left ventricular dilation was confirmed, and the reduced wall  
91 motion of the apex also improved (Figure 4). Cardiac catheterization performed 1 year after  
92 surgery revealed that no stenosis was observed in the left main coronary artery, left anterior  
93 descending artery, and left circumflex artery and antegrade development of the coronary  
94 artery from the apex to the lateral wall that was scarce before surgery (Figure 2c). Further, no  
95 collateral vessels originating from the right coronary artery were noted (Figure 2d). The

96 pulmonary artery pressure and pulmonary artery wedge pressure improved, suggesting an  
97 improvement in cardiac function. In terms of papillary muscle dysfunction, the MR is  
98 currently being treated with angiotensin-converting enzyme inhibitors to prevent left  
99 ventricular enlargement. The pediatric post-repair moderate MR will be improved as the left  
100 ventricle will be developed by remodeling in the future because there is no residual  
101 coaptation failure of the mitral valve.

102

### 103 **Discussion**

104 Pulmonary sequestration is a rare congenital malformation characterized by nonfunctioning  
105 lung tissue separated from the normal lung tissue and fed by an aberrant artery.<sup>7)</sup> There is no  
106 clear traffic between the normal bronchus and the sequestered lung. However, it has been  
107 reported that emphysematous changes occurred in both the sequestered lung and the adjacent  
108 normal lung, and that traffic was caused by abnormal bronchi and fistulas.<sup>8)</sup> It is probable that  
109 the hyperinflated region was generated by the same mechanism in this case as well. Intralobar  
110 pulmonary sequestration is associated with malformations of other organs in 14% of the cases  
111 and cardiac malformations, including macrovasculature in 2.0%.<sup>9)</sup> Three cases of intralobar  
112 pulmonary sequestration associated with heart malformation that were performed lobectomy  
113 were reported, although none with LMCAO was found. A 25-year-old man diagnosed with  
114 aortic valve stenosis (bicuspid valve) 5 months after birth underwent aortic commissurotomy.

115 However, intralobar pulmonary sequestration was not diagnosed, and congestive heart failure  
116 developed. Left lower lobectomy was performed, following which the clinical symptoms  
117 improved.<sup>10)</sup> A 2-month-old infant presented with cyanosis and severe respiratory failure.  
118 Scimitar syndrome, patent ductus arteriosus, and intralobar pulmonary sequestration of the  
119 right lower lobe were detected, and the patient underwent right lower lobectomy at 8 years of  
120 age.<sup>11)</sup> In another report, a newborn baby had tetralogy of Fallot and intralobar pulmonary  
121 sequestration. Right lower lobectomy was performed at 15 months.<sup>11)</sup> In the present case, it  
122 was considered that excess shunt blood flow from the sequestered lungs exacerbated MR and  
123 left ventricular dysfunction in addition to LMCAO. Since coil embolization to treat  
124 pulmonary sequestration has been reported, there may have been the option of preoperative  
125 coil embolization.<sup>12)</sup>

126 Echocardiography revealed persistent MR; however, left ventricular end-diastolic diameter,  
127 left ventricular end-systolic diameter, and the serum level of BNP improved after left main  
128 coronary artery reconstruction and mitral valve annuloplasty, followed by left lower  
129 lobectomy and ligation of the aberrant artery (Figure 3). Although cardiac surgery  
130 significantly contributed to the left cardiac blood supply and preload, it is possible that the  
131 ligation of the aberrant artery and the resection of a sequestered lung contributed to the  
132 improvement of cardiac functions and prevented future exacerbations of heart failure.

133 Since multiple surgeries are burdensome in children, pulmonary surgery can be performed at

134 the same time as cardiac surgery. However, it is necessary to change the operative position  
135 during surgery. The risk of lengthy surgery, postoperative bronchial fistula after lobectomy,  
136 and the possibility of infection, particularly in the sternum, may be increased. Furthermore,  
137 LMCAOs have an early critical stage in infancy. In the left main coronary artery atresia, the  
138 collateral blood flow from the apex to the lateral wall might not keep up with the rapidly  
139 growing myocardial muscles, resulting in myocardial ischemia.<sup>13)</sup> Similar outcomes are  
140 possible in this case. In the present case, the patient had a lower limit of normal cardiac  
141 functions. Therefore, we believe that the timing of sequential surgeries was appropriate.

142

### 143 **Conclusion**

144 After sequential surgeries, including left main coronary artery reconstruction and mitral valve  
145 angioplasty followed by left lower lobectomy and ligation of the aberrant artery, the  
146 enlargement of the left ventricle was improved. It is expected to contribute to the prevention  
147 of future exacerbations of left heart failure.
