Abstract

Background Cancer-testis antigens (CTAs) are often expressed in tumor and testicular tissues but not in other normal tissues. To date, there has been no comprehensive study of the expression and clinical significance of CTA genes associated with endometrial cancer (EC) development. Additionally, the clinical relevance, biological role, and molecular mechanisms of the CTA gene TTK protein kinase (*TTK*) in EC are yet to be fully understood.

Methods Using bioinformatics methods, we comprehensively investigated the genomic, transcriptomic, and epigenetic changes associated with aberrant TTK overexpression in EC samples from the TCGA database. We further investigated the mechanisms of the lower survival associated with TTK dysregulation using single-cell data of EC samples from the GEO database. Cell functional assays were used to confirm the biological roles of TTK in EC cells.

Results We identified 80 CTA genes that were more abundant in EC than in normal tissues, and high expression of *TTK* was significantly linked with lower survival in EC patients. Furthermore, ROC analysis revealed that TTK could accurately distinguish stage I EC tissues from benign endometrial samples, suggesting that TTK has the potential to be a biomarker for early EC detection. We found *TTK* overexpression was more prevalent in EC patients with high-grade, advanced tumors, serous carcinoma, and *TP53* alterations. Furthermore, in EC tissue, TTK expression showed a strong positive correlation with EMT-related genes. With single-cell transcriptome data, we identified a proliferative cell subpopulation with high expression of TTK and known epithelial–mesenchymal transition (EMT)-related genes and transcription factors. When proliferative cells were grouped according to *TTK* expression levels, the overexpressed genes in the *TTK*^{high} group were shown to be functionally involved in the control of chemoresistance. Utilizing shRNA to repress TTK expression in EC cells resulted in substantial decreases in cell proliferation, invasion, EMT, and chemoresistance. Further research identified microRNA-21 (miR-21) as a key downstream regulator of TTK-induced EMT and chemoresistance. Finally, the TTK inhibitor AZ3146 was effective in reducing EC cell growth and invasion and enhancing the apoptosis of EC cells generated by paclitaxel.

Conclusion Our findings establish the clinical significance of TTK as a new biomarker for EC and an as-yet-unknown carcinogenic function. This present study proposes that the therapeutic targeting of TTK might provide a viable approach for the treatment of EC.

Keywords Cancer biomarker, Cancer diagnosis, Prognostic marker, TTK, microRNA-21, EMT, Endometrial cancer

Introduction

Endometrial cancer (EC) is a prevalent type of cancer affecting women globally. According to statistics from 2020, there were approximately 417,000 new cases and 97,000 deaths of EC reported, ranking it as the sixth most common cancer among women [1]. Despite the favorable prognosis for patients with early-stage tumors, who have a 5-year survival rate of more than 75%, advanced EC has a poorer prognosis with a 5-year survival rate of only 20–26% for stage advanced EC patients [2]. This highlights the importance of comprehending the molecular processes of EC and identifying sensitive and specific markers for early detection, prognostic prediction, personalized treatment, and ultimately, improved patient outcomes.

Current standard first-line chemotherapy for EC relies heavily on the combination of carboplatin and paclitaxel. It can achieve remission ratios of 43–62% [3], which implies that 40–60% of individuals continue to demonstrate chemoresistance, significantly decreasing their survival. Resistance to chemotherapeutic medicines necessitates the development of novel methods for enhancing their sensitivity. Cancer cells that undergo epithelial-mesenchymal transition (EMT) acquire mesenchymal features, immune evasion, cancer stem cell maintenance, cancer metastasis, and chemoresistance [4]. Targeting EMT inducers, such as EZH2 and BMI-1, may prevent cancer metastasis and improve the effectiveness of anti-cancer drugs [4, 5].

Cancer-testis antigen (CTA) is a wide family of cancer-specific antigens that express proteins only in human germ line cells of the testis and a variety of human malignancies [6]. CTA antigens have been discovered as potential biomarkers for cancer diagnosis and treatment due to their highly immunogenic, cancer-specific expression pattern [7]. Previously, CAGE, a CTA, was shown to be expressed in EC cell lines (Ishikawa and HEC-1), but not in normal melanocyte cell lines [8]. In addition, the protein expression of another CTA HIWI was detected in EC tissues by using immunohistochemistry [9]. A systematic investigation of the expression and clinical significance of CTA genes involved in EC development is yet lacking.

TTK is a CTA that plays a critical role in driving EMT and chemoresistance in human malignancies [10, 11]. Pharmacological inhibition and genetic silencing of TTK not only reversed the EMT process, but also

greatly reduced invasion in triple-negative breast cancer cells [10]. In ovarian cancer, knockdown or inhibition of TTK expression was known to drastically restrict cell growth and eliminate cisplatin resistance [11]. TTK has been identified as a poor prognostic biomarker in EC by recent investigations [12]. Although a TTK inhibitor (NTRC0066-0) has been shown to greatly reduce the growth of the EC cells [13], the detailed cellular function of TTK in EMT and the progression of EC, as well as the significance of TTK inhibitors in the treatment of EC, remain unknown.

Molecular approaches, such as microarray gene expression profiling and next-generation sequencing, have dramatically improved genome-wide analyses of tumor gene expression patterns and, as a result, have been widely used in developing new diagnostic, prognostic, and predictive biomarkers [14]. The Cancer Genome Atlas (TCGA) database has a wealth of large-scale gene expression data on gynecological malignancies. Current cancer biomarkers discovered by meta-analysis may be of little therapeutic use, perhaps due to a lack of functional validation of biomarker genes.

The key questions that need to be resolved are: (1) the expression pattern of CTA genes in EC; (2) the function of TTK in the development of EC and drug resistance; (3) the molecular mechanisms by which TTK promotes the development of cancer and chemoresistance; and (4) the discovery of effective TTK inhibitors for the treatment of EC.

In this study, we sought to comprehensively examine the expression and prognostic significance of CTA genes involved in EC development. This research also characterized the cellular functions and underlying processes of TTK in regulating cell proliferation, invasion, and paclitaxel (TX) chemoresistance. Finally, we attempted to give a theoretical basis for the future use of a combination of TX and a TTK inhibitor, AZ3146, in the treatment of EC. We discovered that several CTA genes (including *TTK*) were discovered to be overexpressed in EC tissues compared to normal tissues. TTK, as a new EC biomarker, has potential diagnostic and prognostic usefulness. We verified that TTK enhances EMT phenotypes and chemoresistance in EC cells by increasing microRNA-21 (miR-21) expression. TTK inhibition with AZ3146 increased EC cell apoptosis

induced by TX. Given the finding of TTK's crucial role in generating EMT and chemoresistance, targeting TTK may be beneficial in treating EC patients.

Methods

Differential gene analysis and weighted gene co-expression network analysis

Differential analysis was performed using *DESeq2* [15] for RNAseq data (TCGA) and *Limma* for microarray data (GSE17025) using $\log_2|\text{fold-change}| > 1$ and $p_{\text{adjust}} < 0.05$ as thresholds to filter differential genes. Based on *WGCNA* [16] package, the top 5,000 protein-coding genes were used to construct a co-expression network by weighted correlation network analysis. After identifying co-expression modules, we identified the hub genes of the modules using thresholds of $GS > 0.2$ and $MM > 0.8$. Weighted Gene Co-expression Network Analysis (*WGCNA*) package [16] (R package, version 1.71) was used to construct a co-expression network based on the first 5000 protein-coding genes. The “pick-SoftThreshold” function was employed to determine the optimal soft threshold for the module construction. The co-expression networks (modules) were formed using the “blockwiseModules” algorithm with a minimum size of 25, a deepSplit of 3 and a mergeCutHeight of 0.25, after ensuring that the R-squared value reached 0.85.

Survival analysis and cox regression

The EC samples from TCGA were divided into two groups based on gene expression: high expression and low expression. This division was performed by using either the median expression of a specific gene or the median average expression of all genes in a module as the dividing line. The survival package was utilized to plot the Kaplan–Meier (KM) curves and compare the survival risk between the two risk groups. Univariate Cox proportional risk regression analysis of survival data for each differential gene between the CTA^{high} and CTA^{low} groups was performed using the *coxph* function of the survival (R package) with a significance threshold set at $p_{\text{adjust}} < 0.05$. Finally, 3 CTA genes with significantly different expressions related to prognosis were found. The gene expression was normalized to Transcripts Per Million (TPM) values before performing the survival analysis and cox proportional hazard regression.

ROC analysis of the TTK gene

For the evaluation of the gene TTK's performance as a classifier, a logistic regression model was fit due to the binary classification nature of the data. A classical Receiver Operating Characteristic (ROC) analysis was performed using the “roc” function of the *pROC* package [17] (version 1.16.2) in R, with the “smooth” parameter

set to TRUE. The performance of the classifier was measured by the size of the Area Under the Curve (AUC).

Tumor immune estimation resource database

Differences in gene expression of TTK in pan-cancer and normal tissues were downloaded from the TIMER database (<https://cistrome.shinyapps.io/timer/>).

The human protein atlas database

The protein expressions of target genes in human normal tissues and tumor tissues were validated via the Human Protein Atlas (HPA, <https://www.proteinatlas.org/>). Pathological images of immunohistochemical staining of target proteins and subcellular localization results can be downloaded from this website.

Mutational spectrum analysis

Based on the somatic mutation data (files in MAF format) of ECs in TCGA, we identified the significantly mutated genes (SMG) using *MutsigCV* [18] with a filtering threshold of $q\text{-value} < 0.1$. *Maftools* [19] and *GenVisR* [20] programs were used to visualize SMGs.

Copy number variation analysis

GISTIC2 [21] was used to determine genes with significant amplification or deletion. The parameter thresholds for fragments with amplification or deletion lengths were $p\text{-adjusted} < 0.25$. *Maftools* were used to visualize dramatically amplified or deleted fragments.

Differential methylation analysis

Using $|\Delta\beta| > 0.2$ and $p_{\text{adjust}} < 0.05$ as thresholds to filter differentially methylated genes, 450K methylation microarray data from EC samples in TCGA were subjected to a differential methylation analysis using *CHAMP* (R package, version 2.20.1) [22]. For differentially expressed genes whose promoters were differentially methylated, we performed correlation analysis using the methylation levels of the differentially methylated positions (DMPs) with the expression of the corresponding genes.

Enrichment analysis

Functional enrichment: the *clusterProfiler* [23] and *kobas3.0* packages were used for GSEA and KEGG enrichment analysis, respectively. Proliferative scoring for RNAseq and microarray data: the top 20 significantly highly expressed genes for proliferative cell subpopulation analysis were screened according to $\log_2\text{FC}$. Single sample gene set enrichment analysis (ssGSEA) was performed using the “gsva” function from the *GSVA* software [24] (version 1.38.2) in R. The parameters for the analysis were set as follows: method as *ssgsea*, *kcdf* as Gaussian, and *abs.ranking* as TRUE.

Single-cell transcriptome data processing

Single-cell expression matrices of 5 EC samples were downloaded from the GEO database (GSE173682). DoubletFinder [25] (version 2.0.3) was applied to infer and remove doublets. Cells with >15% of mitochondrial genes or <200 or >6000 expressed genes were considered doublets and removed. Besides, we also removed all ribosomal genes. We used Seurat 4.0.1 [26] (resolution = 1, PC = 1:30) to downscale and cluster single-cell expression data after removing batch effects using the harmony [27] package. Cell types were defined by using SingleR and classical cell markers. The FindAllMarker function was used to identify highly expressed genes in each subpopulation with the following parameters: $\log_2|\text{fold-change}| > 0.25$ and $p_{\text{adj}} < 0.05$.

Estimation of CNV analysis and malignant epithelial cell inference

Copy number variations (CNVs) were detected using the InferCNV software [28] (version 1.6.0) in R. The raw count matrix was used as input data, and the endothelial cells were used as the reference (normal). The “run” function was used to infer CNVs in the epithelial cells, with parameters set as cutoff as 0.1, cluster_by_groups, and denoise set as TRUE.

Cell culture

HEC-1 cells were received from the JCRB Cell Bank (Osaka, Japan), while Ishikawa cells were obtained from the American Type Culture Collection (Manassas, VA, USA). Benign endometrial epithelial cells (EM) were kindly provided by Dr. Satoru Kyo (Shimane University, Japan). These cells were maintained at 37 °C with 5% CO₂ in DMEM/F12 media (Sigma-Aldrich, St. Louis, MO, USA) containing 10% fetal bovine serum (FBS, Thermo Fisher Scientific, Carlsbad, CA, USA) and 100 g/ml Normocin (Invivogen, San Diego, CA, USA).

RNA extraction and real-time quantitative PCR

The TRIzol reagent (Thermo Fisher Scientific) was used to isolate RNA, and the concentration and purity of the samples were evaluated using the NanoDrop ND-2000. Reverse transcription was performed on RNA using a Reverse Transcription Kit (Takara, Shiga, Japan). PrimeScript RT-PCR kit (Takara) was used in the qPCR experiments. The primers (as stated below) were retrieved from the PrimerBank database: human *TTK*, forward (F) 5'-GTGGAGCAGTACCACTAGAAATG-3'; reverse (R): 5'-CCCAAGTGAACCGGAAAATGA-3'; human *CK-18*, F: 5'-GGCATCCAGAACGAGAAGGAG-3'; R: 5'-ATTGTCCACAGTATTTGCGAAGA-3'; human *BMI-1*, F: 5'-CCACCTGATGTGTGTGCTTTG-3'; R: 5'-TTCAGT

AGTGGTCTGGTCTTGT-3'; human *EZH2*, F: 5'-AATCAGAGTACATGCGACTGAGA-3'; R: 5'-GCTGTA TCCTTCGCTGTTTCC-3'; human *ZO-1*, F: 5'-CAACATACAGTGACGCTTCACA-3'; R: 5'-CACTATTGACGTTTCCCCACTC-3'; human *Vimentin (VIM)*, F: 5'-AGTCCACTGAGTACCGGAGAC-3'; R: 5'-CATTTCACGCATCTGGCGTTC-3'; human *Fibronectin (FN)*, F: 5'-CGGTGGCTGTCAGTCAAAG-3'; R: 5'-AAACCTCGGCTTCCTCCATAA-3'; human *β -actin*, F: 5'-CATGTACGTTGCTATCCAGGC-3'; R: 5'-CTCCTTAATGTCACGCACGAT-3'. The expression of genes was normalized to β -actin mRNA expression. The NCode EXPRESS SYBR GreenER microRNA qRT-PCR Kit (Thermo Fisher Scientific) was used to verify miRNA expression with miR-21 forward primer and universal qRT-PCR Primer (Thermo Fisher Scientific). The expression of miR-21 was normalized to the levels of U6.

Cell transfection

2 μ g of TTK overexpression vector and the corresponding control vector (Origene, Rockville, MD, USA) or 2 μ g of TTK-targeting shRNAs (sc-36758-SH, Santa Cruz Biotechnology) and a control shRNA (sc-108060, Santa Cruz Biotechnology) were used per well for 12-well plates to transfect Ishikawa and HEC-1 cells using the Lipofectamine 3000 transfection reagent (Thermo Fisher Scientific). Thermo Fisher Scientific provided the miR-21 mimic/inhibitor (30 nM) and the control mimic/inhibitor (30 nM), which were transfected into EC cells using the Lipofectamine 3000 transfection reagent.

Western blotting

EC cells were lysed using M-Per Mammalian Protein Extraction Reagent (Pierce, Rockford, IL, USA). By 10% SDS-polyacrylamide gel electrophoresis, protein samples (20 μ g) were separated and transferred to a PVDF membrane (Millipore, Bedford, MD, USA). The membrane was incubated for 2 h overnight at 4 °C with a primary antibody against human TTK (1:1000; Cell Signaling Technology, Beverly, MA, USA) or β -actin (1:5000, Cell Signaling Technology), followed by 1 h at room temperature with a secondary antibody. The band was evaluated using enhanced chemiluminescence detection reagents (Pierce, Rockford, IL, USA).

Functional assays

Cell proliferation was determined using the Cell Counting Kit-8 (CCK-8) assay (Dojindo, Japan). After 72 h, 10 μ l of CCK-8 reagent was applied to the experimental cell-containing wells and incubated for up to 4 h before determining the absorbance at 450 nm. The cell invasion assay was carried out in a Matrigel-coated transwell chamber with a pore size of 8 μ m (Corning Costar,

Lowell, CA, USA). The bottom compartment was filled with growth medium supplemented with 10% FBS, and the transwell inserts were seeded with 5×10^4 cells suspended in serum-free culture media. Cells were cultured at 37 °C for 24 h before being fixed in paraformaldehyde and stained with crystal violet. Using an upright Nikon microscope, invaded cells were observed and photographed.

Cytotoxicity of the TTK inhibitor AZ3146

In 96-well plates, 5000 EC cells per well were seeded and left to adhere overnight. These cells were treated for an additional 24 h with or without AZ3146 (sc-361114, Santa Cruz Biotechnology) at doses ranging from 0 to 90 nM. MTT assays (BioAssay Systems, Hayward, CA, USA) were used to assess cell viability.

Investigation of cell apoptosis

The Caspase-Glo 3/7 Assay kit (Promega, Madison, WI, USA) was used to quantify apoptotic activity in EC cells. EC cells were allowed 24 h to adhere to the plate. In 100 μ l of medium, HEC-1 and Ishikawa cells were treated with TX as indicated in the presence of AZ3146 or DMSO for 24 h. 100 μ l of luminescence substrate for Caspase-3/7 was then added to each well and stirred gently. After 90 min of incubation at room temperature and in the dark, luminescence was measured using a microplate reader (Thermo Fisher Scientific).

Statistical analysis

Using the Kaplan–Meier approach, survival curves were created and analyzed using the log-rank tests. Two-tailed Student's *t*-tests and Wilcoxon tests were used when appropriate. The error bars show the standard error of the mean collected from at least three different experiments. When *P*-values were less than 0.05, the results were considered significant. All graphs were plotted based on R 4.0.4.

Results

Identification of EC-associated CTA genes

In total, 255 CTA genes were retrieved from the CTDatabse [29]. The transcriptional levels of these genes in EC tissues were compared to those in normal endometrial tissues using the TCGA database. In EC, 80 CTA genes were upregulated, whereas 17 genes were downregulated (Fig. 1A). We performed ssGSEA analysis using upregulated 80 CTA genes based on transcriptomic data from TCGA EC samples and grouped EC samples according to enrichment scores. Clinical association analysis showed that tumors with late-clinical stage and high grade, as well as mixed and serous tumors, tended to be significantly enriched in the group with high CTA score (CTA^{high}) (Fig. 1B). In addition, the CTA^{high} group was substantially associated with shorter overall survival (especially in the first 10 years) in EC patients (Fig. 1C). Further differential gene analysis revealed that 45 of the 80 CTA genes were significantly highly expressed in the CTA^{high} group (Fig. 1D, E). To explore the main factors contributing to the considerably lower survival in the CTA^{high} group, we performed univariate cox regression on 45 upregulated genes and found three of them (*TTK*, *LY6K*, and *NOL4*) contributed to poor outcomes (Fig. 1F).

We obtained microarray data from the Gene Expression Omnibus (GEO) microarray dataset (GSE17025) cohort, which contains EC stage I and benign endometrial samples. *TTK* was shown to be significantly higher in stage I EC tissues compared to benign endometrial tissues, while the other two genes were not significantly differentially expressed in different tissues (Fig. 1G). Our survival analysis showed that high *TTK* expression was significantly associated with shorter overall survival in EC patients (Fig. 1H). In addition, *TTK* expression could also be used to distinguish early-stage EC tissues from normal tissues, with an AUC of 0.873 for early EC diagnosis (Fig. 1I). Our data showed that *TTK* is upregulated in EC and could be a potential biomarker for EC diagnosis and prognosis prediction. Therefore, *TTK* was chosen for further research.

(See figure on next page.)

Fig. 1 Identification of EC-associated CTA genes. **A** Differential genes between tumor and para-cancer; Red dots indicate genes significantly overexpressed in the tumor, and blue dots indicate genes significantly downregulated in para-cancer. The screening threshold is $(\log_2[\text{fold-change}] > 1$ and $p\text{-adjust} < 0.05$). The horizontal gray dashed line means $p\text{-adjust} = 0.05$, and the vertical gray dashed line means $\log_2[\text{fold-change}] = 1$. **B** ssGSEA enrichment analysis based on CTA genes that upregulated in EC showed a strong correlation between CTA enrichment scores and clinical features. **C** Results of survival analysis based on CTA enrichment scores. A two-sided log-rank test is used to compare patient survival between the two groups. **D** Differential genes between the CTA^{high} group and CTA^{low} group; red dots indicate genes significantly overexpressed in the CTA^{high} group, and blue dots indicate genes significantly overexpressed in the CTA^{low} group; the screening threshold is $(\log_2[\text{fold-change}] > 1$ and $p\text{-adjust} < 0.05$). The horizontal gray dashed line means $p\text{-adjust} = 0.05$, and the vertical gray dashed line means $\log_2[\text{fold-change}] = 1$. **E** Heat map shows the CTA genes that are co-upregulated in the CTA^{high} group and EC. **F** Univariate cox regression analysis of the CTA gene in E plot. **G** Differential gene expression of three genes (*TTK*, *LY6K*, *NOL4*) in stage 1 EC tissues (GEO database) and benign samples (GSE17025). *** $P < 0.001$, by Wilcoxon tests. **H** Survival analysis of *TTK* based on EC gene expression profile from TCGA database. A two-sided log-rank test is used to compare patient survival between the two groups. **I** *TTK* expression has potential diagnostic significance in distinguishing early-stage EC tissues from benign tissues. The ROC curve was created using gene expression data from GSE17025

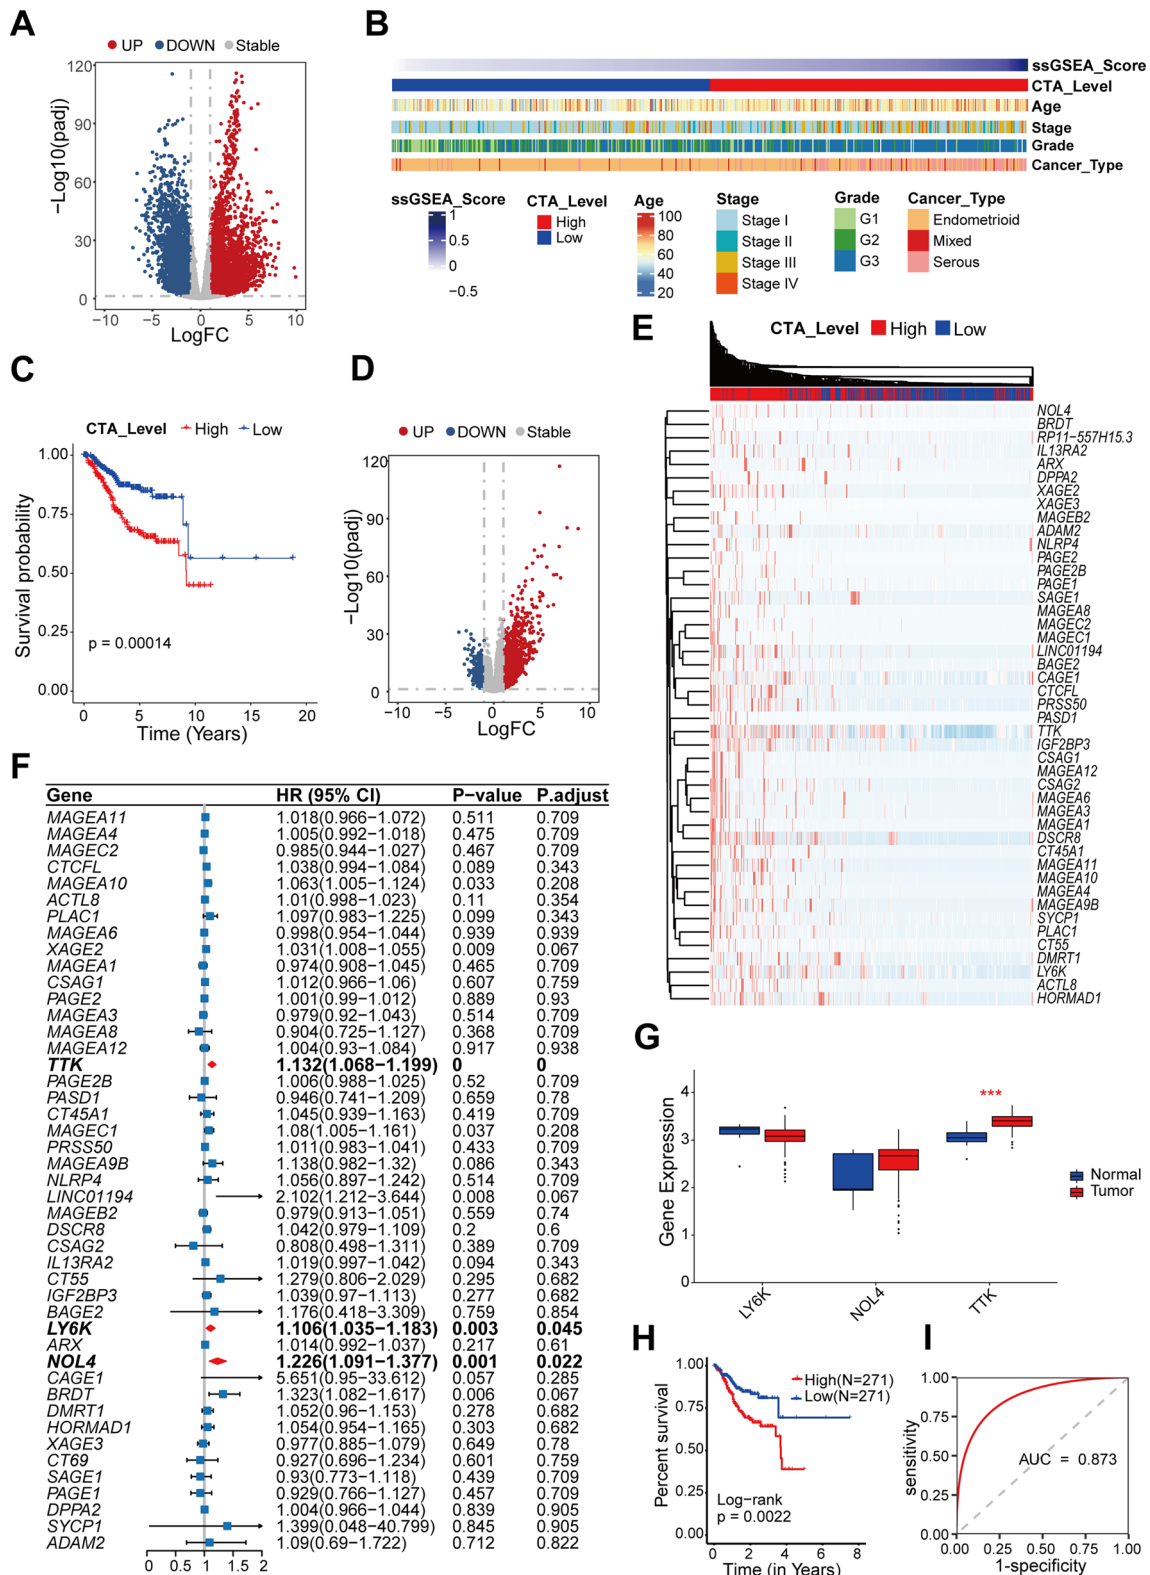

Fig. 1 (See legend on previous page.)

Aberrant *TTK* overexpression is linked to aggressive phenotypes in EC

The TIMER1.0 database was used to examine the *TTK* mRNA expression levels in pan-cancers. The mRNA expression of *TTK* was significantly higher in almost all tumor types in TCGA compared to normal samples (Fig. 2A). *TTK* was expressed abundantly in EC samples with higher clinical stage and grade, but much less in ECs with lower clinical stage and grade (Fig. 2B). Serous EC, a rare but more aggressive subtype of EC, had a much higher level of *TTK* expression than endometrial endometrioid carcinomas (EECs) (Fig. 2C). In stage I EC samples (GSE17025), we validated that *TTK* levels were considerably increased in serous tumors than in EEC tumors (Fig. 2D). Using the Human Protein Atlas (HPA) database, we further investigated *TTK* protein expression in ECs. *TTK* levels in EC tissues were much higher than in adjacent normal tissues (Fig. 2E). In addition, the results of subcellular localization in the HPA database indicate that *TTK* was mainly localized in the nucleoli and cytosol (Fig. 2F). The qRT-PCR and western blotting experiments were then used to assess *TTK* expression levels in EM, a normal endometrial cell line, and two representative EC cell lines (Ishikawa and HEC-1). *TTK* mRNA and protein levels were significantly higher in the EC cell line compared to the EM cells (Fig. 2G, H). These results showed that high *TTK* expression is a promising biomarker for predicting aggressive EC.

Involvement of *TTK* in the progression of the cell cycle in EC

To investigate the biological function of *TTK* in EC, we performed co-expression network analysis (WGCNA) based on gene expression profiles of EC (Fig. 3A) and did KEGG enrichment for genes in each module (Fig. 3B). We found the most significant correlation between *TTK* and the green module (Pearson correlation = 0.76, $P = 5.1e-103$), which is mostly involved in cell cycle and DNA replication-related pathways (Fig. 3B). The results of univariate cox regression of the modules indicated that increased gene expression in the green module was strongly associated with shorter overall survival in EC patients (Fig. 3C), and this result was confirmed by the results of survival analysis (Fig. 3D). Meanwhile, we

performed protein–protein interaction (PPI) network analysis on nine hub genes of the green module (Fig. 3E). The results of PPI analysis indicated that there were strong interactions among the hub genes in the green module (Fig. 3F).

By survival analysis, we found that high expression of three of the nine hub genes (*CDC48*, *FAM83D*, and *RACGAP1*) was significantly associated with shorter overall survival (Additional file 1: Fig. S1A) and progression-free survival (Additional file 1: Fig. S1B) in EC patients. Similar to *TTK*, mRNA (Additional file 1: Fig. S1C) and protein (Additional file 1: Fig. S1D) expression of these three genes were significantly elevated in EC samples. Subcellular localization showed that *CDC48* was mainly localized in the nucleolus (Additional file 1: Fig. S1E). *FAM83D* was found in the mitotic spindle, and *RACGAP1* was seen in the nucleoplasm. These results implicated the functions of these three proteins during mitosis.

In addition, we divided EC samples into *TTK*^{high} and *TTK*^{low} groups according to the gene expression level of *TTK* and performed differential expression analysis between the two groups (Fig. 3G). We found significant activation of cell proliferation-related pathways (including E2F Targets, G2M Checkpoint, Mitotic Spindle, MYC Targets V1/V2 pathways) in the *TTK*^{high} group according to GSEA enrichment analysis (Fig. 3H). *TTK* has been reported to maintain chromosome stability in mitosis and plays a critical role in chromosome alignment and spindle assembly checkpoints [30]. In addition, *TTK* could protect aneuploid cells from mitotic catastrophe, which leads to the development of aneuploid tumors [31]. These analyses imply that *TTK* facilitates the division of genomically unstable tumor cells to sustain the proliferation and progression of EC cells.

Genomic and epigenetic alterations associated with *TTK* dysregulation in EC

To explore the genomic alterations related to *TTK* dysregulation in EC, we comprehensively analyzed the mutational landscape and compared between *TTK*^{high} and *TTK*^{low} groups based on somatic mutation data from TCGA EC samples (Fig. 4A). The results revealed no significant difference in tumor mutational burden (TMB)

(See figure on next page.)

Fig. 2 Aberrant *TTK* overexpression is linked to aggressive phenotypes in EC. **A** Differential analysis of *TTK* expression in TCGA pan-cancer. **B, C** Differential analysis of *TTK* expression in TCGA EC patients, as divided by tumor stage (**B**, left panel: stage I, stage II, stage III, and stage IV), tumor grade (**B**, right panel: G1, G2, and G3), as well as the histologic type (**C**; EEC: endometrioid; serous; mixed-type). **D** The GEO database was used to show increased *TTK* expression in serous ECs. The comparison was conducted using Wilcoxon tests. * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$. **E** An immunohistochemical picture from the HPA database demonstrates high *TTK* protein expression in EC tissues than in adjacent normal tissues. **F** Results of subcellular localization of *TTK* protein, green indicates target protein, blue indicates nucleus and red indicates microtubule. Scale bars = 20 μm . **G, H** The mRNA (**G**) and protein (**H**) expression of *TTK* in two EC cell lines and a normal cell line EM were investigated using qRT-PCR and western blotting. *** $P < 0.001$, by Student's *t*-tests

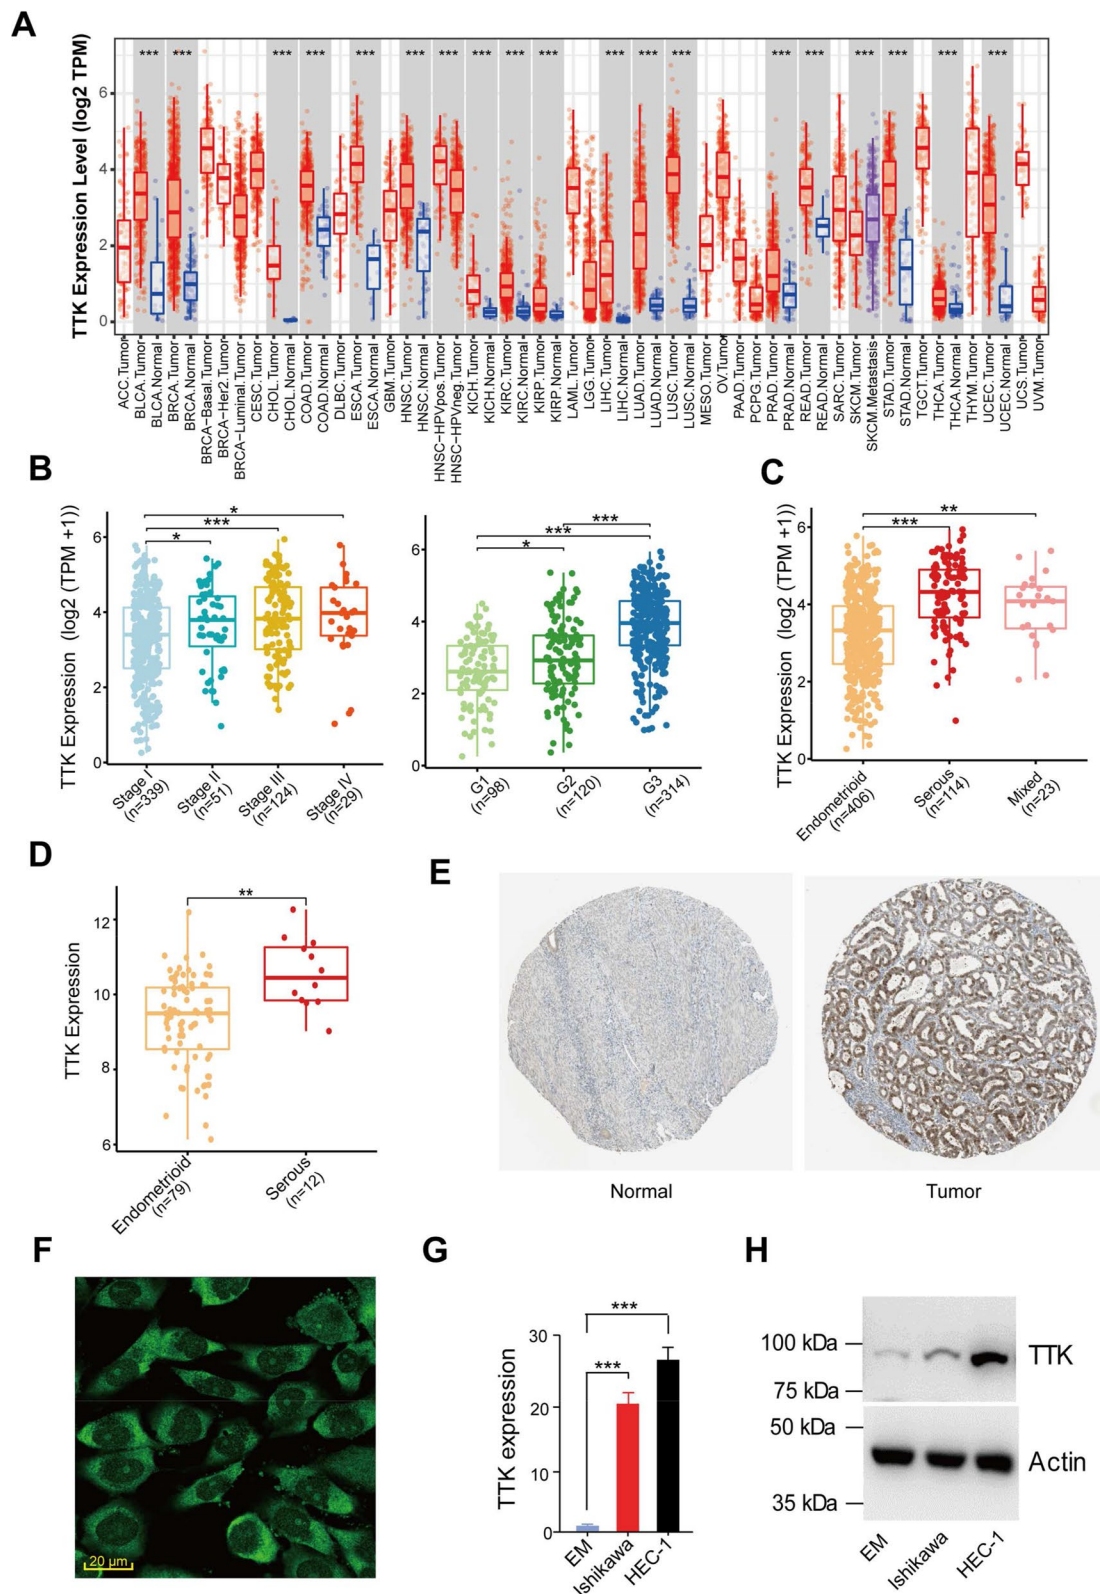

Fig. 2 (See legend on previous page.)

between the two groups of samples (Fig. 4B). In addition, we identified significantly mutated genes (SMGs) in the two groups of samples using MutsigCV (Additional file 1: Fig. S2A, B). The results of the fisher's test suggested a significant difference in the mutation profiles of the two groups (Fig. 4C). The *TP53* mutation was significantly enriched in the TTK^{high} group, with a high mutation frequency of 53% (Fig. 4D). Further analysis revealed that *TTK* expression was significantly higher in the *TP53* mutated group than others in ECs of TCGA (Fig. 4E). In addition, ECs from the TTK^{high} group had substantially higher tumor purity than that of the TTK^{low} group (Additional file 1: Fig. S2B). It's suggested that dysregulation of *TTK* expression in ECs was related to *TP53* mutations, which contributed to the persistent proliferation of tumor cells.

On the other hand, we compared the differences in copy number variations (CNVs) between the two groups based on CNV data (Fig. 4F) and compared the number of amplified and missing CNVs between the two groups of samples, respectively. We found that the number of both amplified and missing CNVs in the TTK^{high} group was significantly higher than that in the TTK^{low} group (Additional file 1: Fig. S2C). The comparison of CNVs showed that significant amplification occurred in the 1q22, 20q11, and 19q12 regions in the TTK^{high} group. In contrast, significant deletions occurred in the 16q21, 4q34, 17p13, 15q21, 9q34, and 9q21 regions in the TTK^{low} group (Additional file 1: Fig. S2D). We also found a significant difference between the population frequencies of CNV occurrence of cancer driver genes in the two sample groups (Additional file 1: Fig. S2E).

To further discover genomic alterations in the *TTK* gene across the pan-cancer population, we conducted gene mutation and copy number alteration analyses using the cBioPortal database. In 32 TCGA investigations, the *TTK* gene was altered in 306 (3%) of 10,953 individuals (Additional file 1: Fig. S3A). Almost all of the TCGA cancer patients had genetic alterations ("mutation and amplification") (Additional file 1: Fig. S3A). Compared to patients with other cancer types, patients with EC had the greatest prevalence of *TTK* alterations (Additional file 1: Fig. S3A). Similar to established oncogenes (such

as *TP53* and *MYC*), *TTK* missense mutation, amplification, and mRNA upregulation were seen in EC using Oncoprint data from cBioPortal (Additional file 1: Fig. S3B). Serous EC demonstrated greater rates of *TTK* gene amplification and *TTK* mRNA overexpression than EEC and mixed tumors (Additional file 1: Fig. S3C).

To explore epigenetic alterations associated with *TTK* dysregulation, we performed a genome-wide methylation analysis of all TCGA EC patients (Additional file 1: Fig. S4A) and found that 59 CpG sites located in the promoter region were differentially methylated (Additional file 1: Fig. S4B). Association analysis with differential genes between the two groups revealed that seven genes in which DMP are located were differentially expressed. Two of these genes (*ANG* and *C4BPB*) showed hypermethylation and down-regulation, and five genes (*BRINP1*, *KLHL1*, *NOLA*, *SLC6A15*, and *PKIA*) showed hypomethylation and up-regulation. Correlation analysis of methylation and gene expression suggested that gene expression of these seven genes was regulated by methylation of CpG sites located in the promoter region (Additional file 1: Fig. S4C, D). Survival analysis showed that low expression of two hypermethylated and down-regulated genes was associated with shorter overall survival in EC patients (Additional file 1: Fig. S4E). In comparison, the other five hypermethylated and up-regulated genes were positively associated with worse survival (Additional file 1: Fig. S4F). These results suggest that the TTK^{high} and TTK^{low} groups show specific methylation profiles and methylation of the promoters of some genes could significantly affect gene expression and consequently affect the survival of patients.

Cell subpopulations associated with dysregulated *TTK* expression in EC

Given that dysregulation of *TTK* expression is closely correlated with malignant proliferation of tumor cells and consequently increased tumor purity, we speculated that *TTK* might alter the proportion of cells in the tumor microenvironment. Based on this hypothesis, we analyzed single-cell transcriptome data of five EC samples from the GEO database. By using reported marker genes [32], we identified a total of 10 cell subpopulations

(See figure on next page.)

(Fig. 5A, B), including epithelial cells, ciliated cells, proliferative cells, fibroblasts, endothelial cells, T cells, B cells, myeloid cells, mast cells, and NK cells.

Since EC is a malignant tumor of epithelial tissue origin, we used endothelial cells as the reference and inferred the CNV levels of epithelial, ciliated, and proliferative cells (Fig. 5C). The results showed that all three types of epithelial cells had amplification in the long arm of chromosome 1, which was consistent with the TCGA EC samples. However, we found different CNV in different types of epithelial cells. Ciliated cells had amplification in the short arm of chromosome 1 independently of the other two subpopulations, and parts of epithelial cells had a partial deletion of chromosome 16. In addition, it appears that a small proportion of normal diploid cells are present in the three types of epithelial cells. Moreover, we explored the expression of hub genes associated with *TTK* dysregulation across different cell types. Surprisingly, *CDCA8*, *FAM83D*, *RACGAP1*, and *TTK* were mainly expressed in proliferative cells (Fig. 5D). Functional enrichment analysis of genes highly expressed in proliferative cells showed that these genes are mainly associated with cell cycle and metabolic pathways (Fig. 5E). Hence, we speculate that this subpopulation may be related to tumor malignant proliferation and metastasis.

High *TTK* expression is positively correlated with EMT signature and chemoresistance in EC

To investigate the effect of different cell subpopulations on EC survival, we performed survival analysis of the top 5 highly expressed genes of all cell subpopulations based on the TCGA gene expression profile (Additional file 1: Fig. S5A). The results showed that only high expression of *UBE2C*, mainly expressed in proliferative cells, was substantially associated with shorter overall survival and progression-free survival of EC patients (Fig. 6A, B). It was reported that *UBE2C* promotes EMT via p53 in EC [33], suggesting that proliferative cells may have EMT phenotypes.

To verify the relationship between *TTK* gene expression and EMT in EC, we performed a correlation analysis of *TTK* and reported EMT-related genes [34] based on the gene expression profiles of TCGA EC data. We found that *TTK* showed a significant and positive correlation with the majority of EMT-related genes (Fig. 6C). We further investigated the expression of 19 genes with a

correlation coefficient above 0.8 with *TTK* at the cellular level. Surprisingly, 18 of the 19 genes were significantly highly expressed in the proliferative cells (Additional file 1: Fig. S5B). In addition, the common EMT transcription factors *EZH2* and *FOXM1* were highly expressed in the proliferative subpopulation. We speculate that proliferative cells in EC might promote EMT by high expression of *TTK*. Therefore, we further performed ssGSEA analysis of EC and normal samples from the TCGA database based on the top 20 genes highly expressed in proliferating cell subpopulations. As expected, EC samples get a significantly higher proliferating score than normal tissues. At the same time, serous ECs are significantly higher than EEC tumors (Fig. 6E). And we also found a similar trend in the early EC samples (GSE17025) (Fig. 6F).

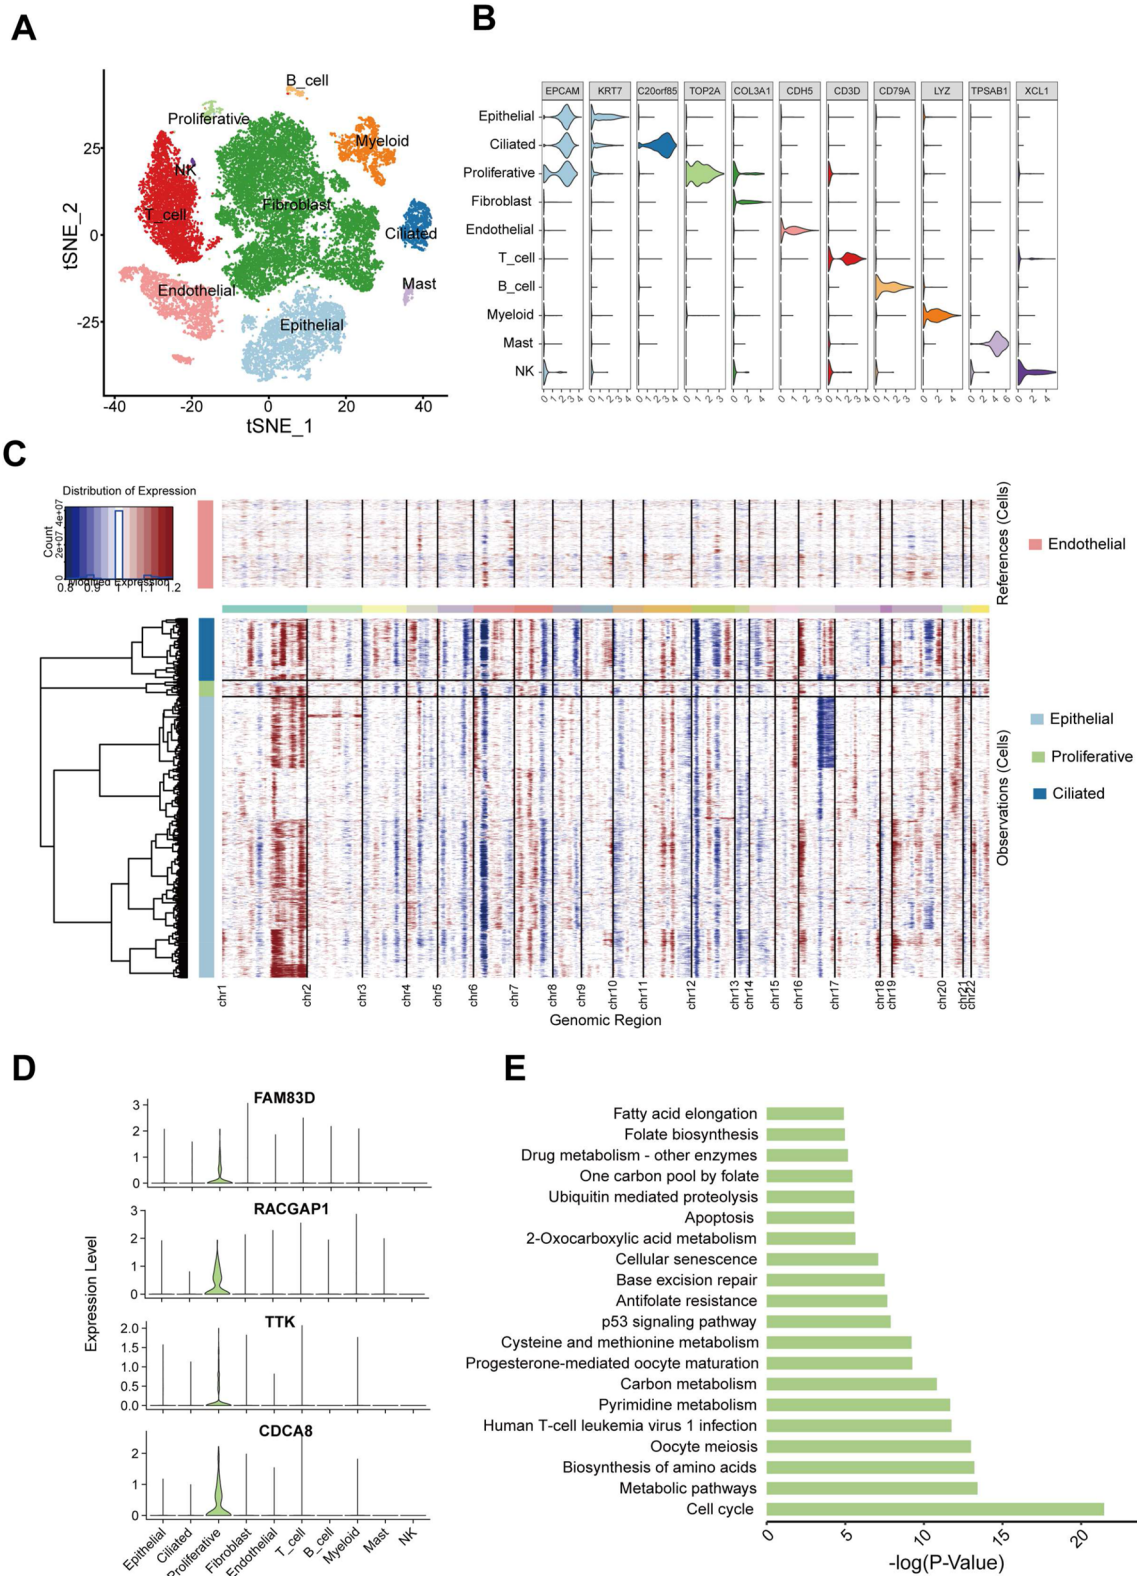

Moreover, we divided all proliferative cells into *TTK*^{high} and *TTK*^{low} groups according to their *TTK* expression levels, and 33 genes were significantly overexpressed in the *TTK*^{high} group, and strong protein–protein interaction exists among these genes (Fig. 6G). KEGG enrichment results suggested that these highly expressed genes may lead to platinum drug resistance (Fig. 6H). *BUB1* and *BUB1B* were highly expressed in proliferative cells (Fig. 6I), and they were shown to be associated with resistance to chemotherapeutic drugs, including TX, in previous studies [35–37]. Correlation analysis of gene expression profiles in TCGA EC samples also suggested that the expression of *TTK* showed a very significant positive correlation with *BUB1* and *BUB1B* (Fig. 6J), suggesting that high expression of *TTK* may lead to chemoresistance.

Inhibition of *TTK* suppresses EMT and chemoresistance of EC cells

Previous research has shown that *TTK* has an important tumor-promoting role in triggering EMT in breast cancer [10] and bladder cancer [38]. As a result, we looked at how *TTK* inhibition affects EC cell proliferation, invasion, and chemoresistance. Two shRNAs were examined for their ability to lower *TTK* expression, and the one with the highest knockdown efficacy was selected for our study. *TTK* shRNA was then transfected into HEC-1 cells. Western blotting demonstrated that shRNA-mediated *TTK* knockdown reduced cell proliferation significantly in HEC-1 cells (Fig. 7A, B). Furthermore, inhibiting *TTK* expression significantly decreased the ability of HEC-1

(See figure on next page.)

cells to invade (Fig. 7C). TTK knockdown dramatically increased the sensitivity of HEC-1 cells to TX (Fig. 7D). The proliferation, invasion, and resistance to TX were consistently enhanced in Ishikawa cells transfected with the TTK-overexpressing vector (Fig. 7A–D). Changes in several EMT-related genes in TTK-overexpressing Ishikawa cells and HEC-1 cells with TTK knockdown were examined to see whether TTK influences the EMT process. In HEC-1 cells with TTK knockdown, qRT-PCR assays demonstrated an increase in epithelial marker *CK-18* and a decrease in recognized EMT inducers (*BMI-1* and *EZH2*) (Fig. 7E). The opposite gene expression patterns were seen in TTK-overexpression Ishikawa cells

(Fig. 7E). We next used the LinkedOmics database to assess whether *TTK* expression was associated with *CK-18*, *BMI-1*, and *EZH2* levels in TCGA EC tissues. In EC samples, we found strong positive associations between *TTK* and *BMI-1* (or *EZH2*) expression (Fig. 7F). *TTK* expression was shown to be negatively associated with *CK-18* expression in EC (Fig. 7F).

To further test the tumor-promoting role of TTK, we conducted a series of experiments to test whether inhibiting TTK activity with its specific inhibitor AZ3146 might replicate the effects of TTK downregulation. The cytotoxicity of the TTK inhibitor AZ3146 was assessed with MTT assays. After 24 h of treatment with different

concentrations of AZ3146 on EC cells, we determined that doses of 30 nM (for HEC-1 cells) or 15 nM (for Ishikawa cells) were cytotoxic (Additional file 1: Fig. S6A). In

later experiments, a subtoxic dose of AZ3146 (28 nM for HEC-1 cells and 14 nM for Ishikawa cells) was used to test its effects on EC cells. CCK-8 experiments revealed

that AZ3146 efficiently inhibited EC cell growth (Additional file 1: Fig. S6B). Subsequent cell invasion studies demonstrated that AZ3146 administration dramatically inhibited cell invasiveness (Additional file 1: Fig. S6C). To determine the influence of AZ3146 on the apoptosis of EC cells, apoptotic assays were used. As expected, the activity of Caspase-3/7 in EC cells was increased upon TX treatment (Additional file 1: Fig. S6D). Interestingly, when EC cells were treated with both TX and AZ3146, Caspase-3/7 activity was further enhanced, suggesting that AZ3146 has a synergistic impact on TX-induced cell apoptosis (Additional file 1: Fig. S6D). All these data suggested that TTK is a unique EMT activator in EC and that inhibition of TTK diminishes the invasive, mesenchymal and chemoresistant properties of EC cells.

TTK induces EMT in EC cells by upregulating miR-21 expression

TTK induces EMT in breast cancer cells by upregulating miR-21 and decreasing miR-200c levels [10]. Thus, we examined the ENCORI database to determine whether *TTK* and miR-21 and miR-200c expression in EC samples were clinically relevant. There was a significant positive relationship between *TTK* mRNA expression and miR-21 (but not miR-200c) expression in 538 EC samples (Fig. 8A). MiR-21 expression was significantly higher in EC tissues than in normal tissues (Fig. 8B). Using qRT-PCR, we also found that miR-21 was expressed at greater levels in EC cells than in a normal cell line EM (Fig. 8C). To investigate whether TTK inhibition affects EMT through miR-21, qRT-PCRs were used to quantify miR-21 levels in EC cells overexpressing TTK or transfected with TTK shRNA. TTK overexpression was shown to increase the expression of miR-21 in Ishikawa cells (Fig. 8D). TTK shRNA transfection resulted in a substantial reduction in miR-21 expression in HEC-1 cells (Fig. 8D). MiR-21 has previously been demonstrated to be overexpressed in EC samples when compared to non-tumor tissues [39], and high miR-21 expression in EC tissues has been associated to poor survival [40]. Furthermore, it has been shown that miR-21 is an EMT activator and that blocking miR-21 in EC cells reverses EMT [43]. To find out whether miR-21 has a role in chemoresistance, EC cells were transfected with either an inhibitor or a mimic of miR-21. The qRT-PCRs validated that miR-21

was downregulated or upregulated in the corresponding EC cells (Fig. 8E). Using a cell viability experiment, we found that miR-21 overexpression reduced the sensitivity to TX in Ishikawa cells, whereas miR-21 deletion in HEC-1 cells eliminated TX resistance (Fig. 8F, G). In Ishikawa cells with miR-21 overexpression, our qRT-PCR tests revealed a reduction in *ZO-1* expression as well as an increase in *VIM* and *FN* abundance (Fig. 8H). In contrast, suppressing miR-21 in HEC-1 cells dramatically increased *ZO-1* expression while decreasing *VIM* and *FN* expression (Fig. 8I). Together, our findings showed that increased miR-21 expression is required for TTK to initiate EMT and chemoresistance.

Discussion

ECs represent very serious health challenges, and new biomarkers are required to allow for early detection, as well as new approaches to improve the sensitivity of chemotherapeutic agents, which could significantly enhance the opportunities for successful cancer treatment and favor a higher chance of cure, survival, and quality of life for patients [3]. Increasing evidence suggests that CTAs play a crucial role in tumorigenesis and progression. Many CTAs are known to promote the progression of tumors through cellular activities such as cell proliferation, division, or cell motility [6, 7]. CTA gene dysregulation is a common occurrence in cancer and significantly decreases the survival of patients [6]. However, the functions of CTA genes and their potential therapeutic uses in EC are currently unclear. In this study, we found that high expression of dysregulated CTA (including *TTK*) genes in EC was significantly associated with the advanced stage of EC and shorter survival. Moreover, our findings hinted at the tumor-promoting functions of TTK in EC (Fig. 9).

Numerous prior research has examined the association between TTK expression and cancer diagnosis [41, 42]. Earlier research demonstrated the diagnostic usefulness of TTK in differentiating liver cancer tissues from normal liver tissues [41]. Increased TTK expression has high diagnostic efficacy for breast cancer screening [42]. However, the potential diagnostic usefulness of the TTK in EC has not been investigated. In our study, we established that TTK had accurate diagnostic utility for stage I EC,

(See figure on next page.)

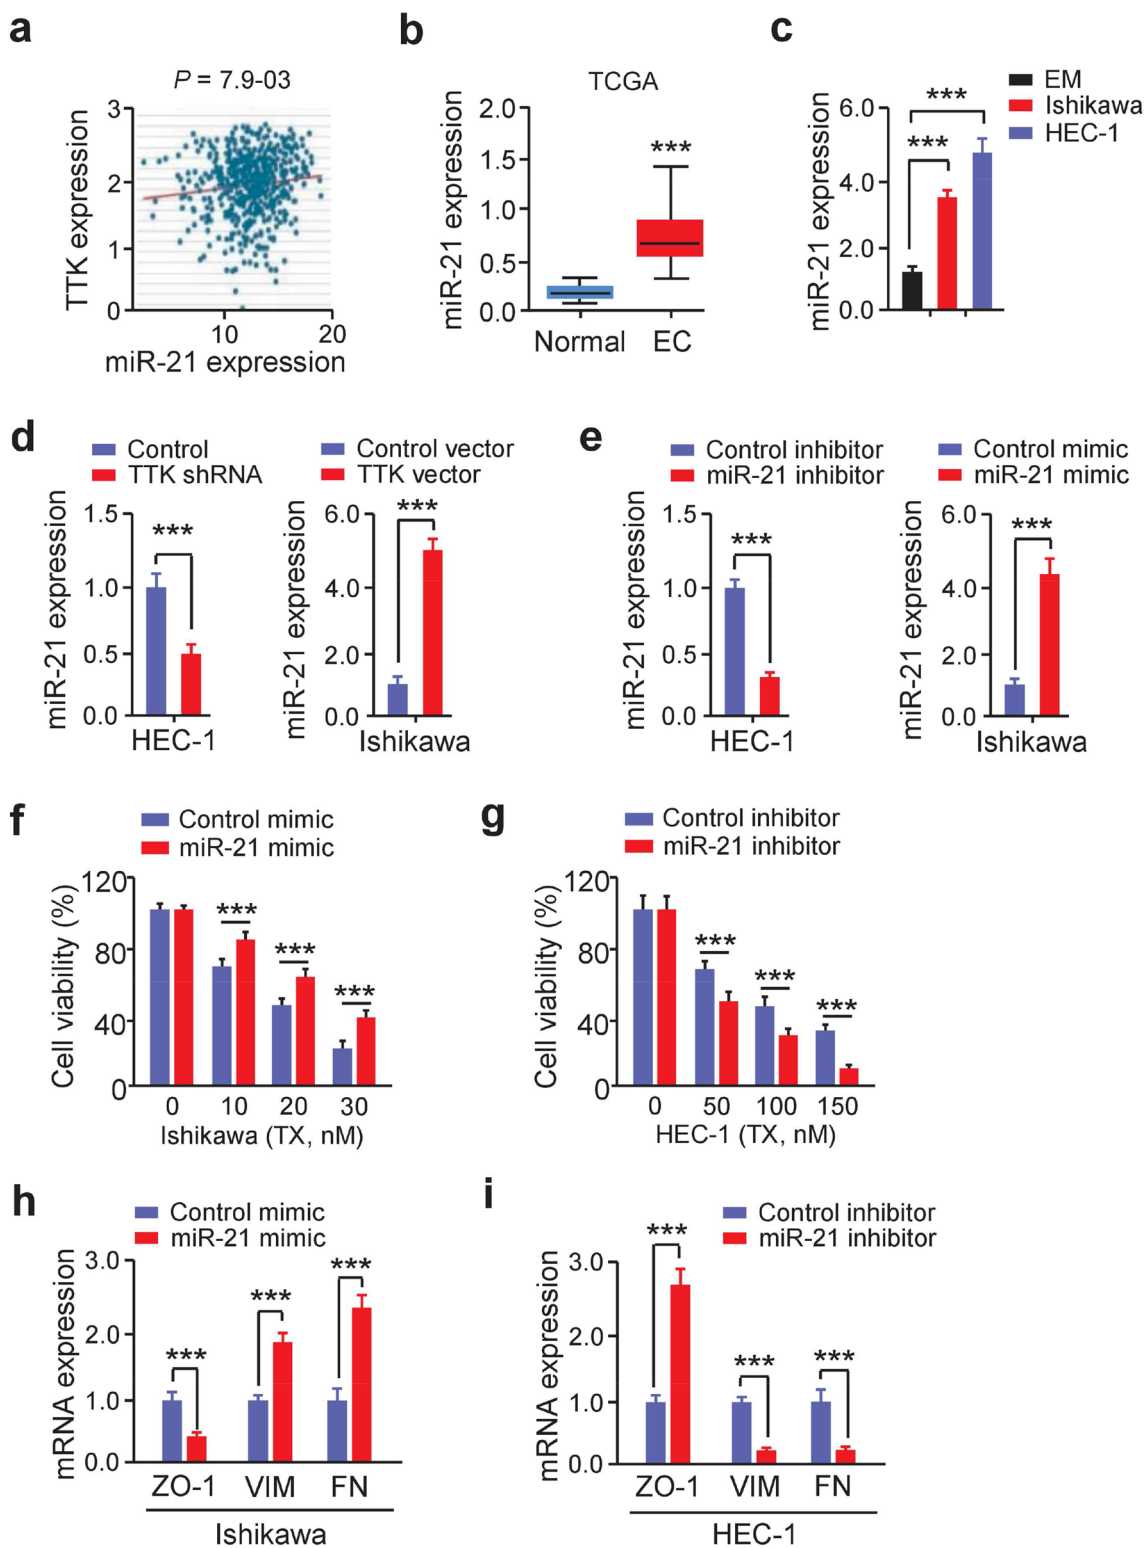

Fig. 8 (See legend on previous page.)

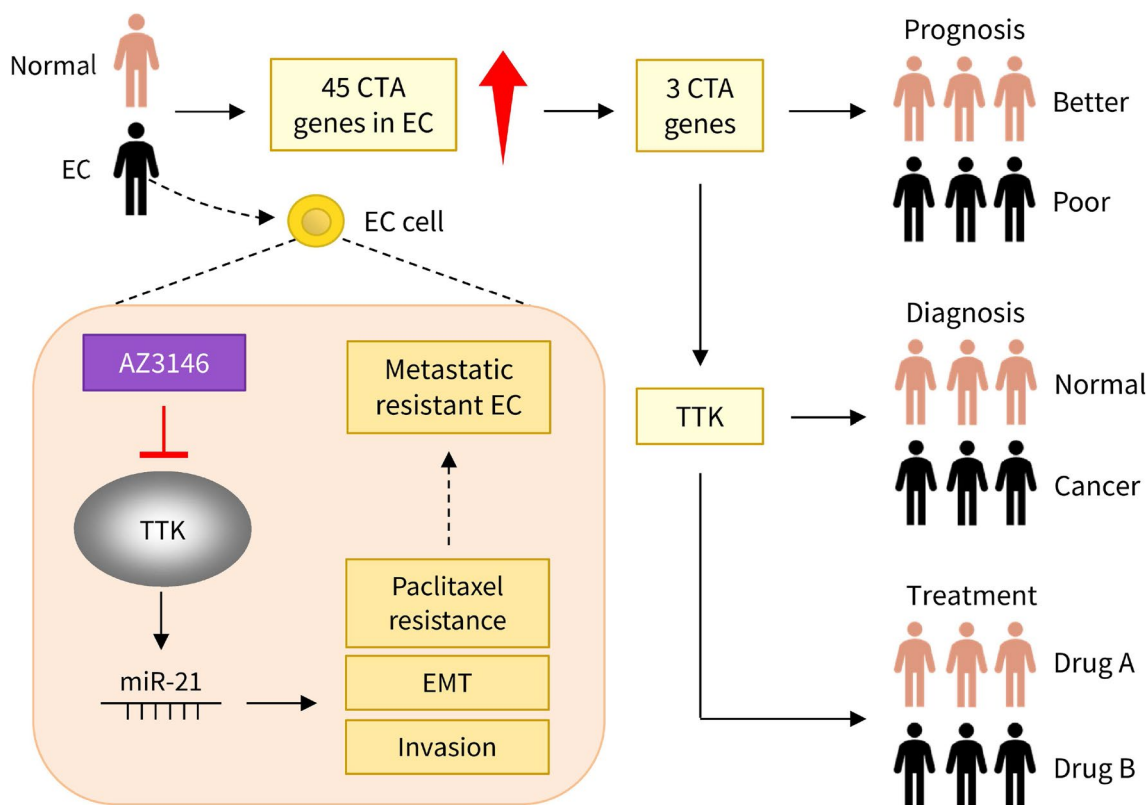

Fig. 9 Illustration demonstrating the role of the TTK/miR-21 pathway in facilitating EMT and conferring chemoresistance in EC. Through a screening process, TTK was discovered to be a potential biomarker and therapeutic target for EC. Higher TTK expression in EC cells leads to increased miR-21 expression, which induces EMT, cell proliferation, and chemoresistance

thus indicating that highly expressed TTK can be used as a valuable biomarker for early diagnosis of EC.

Previous studies involving TTK have not only examined its value for cancer diagnosis, but also analyzed its role in determining the prognosis of cancer patients. A higher histological stage, a greater number of metastatic lymph nodes, and a shorter 5-year overall survival in lung cancer are all linked to high TTK expression [43]. In addition, overexpression of TTK is connected to cancer progression and poor prognosis in triple-positive breast cancer patients [44]. In ovarian cancer tissues and cells, TTK expression was upregulated, and its overexpression was discovered to be related to an unfavorable prognosis in ovarian cancer patients [45]. Based on our findings, patients with EC who have high TTK expression have a worse probability of surviving. Consequently, our study emphasized the potential role of TTK in assessing EC outcomes (Fig. 9).

TTK plays a significant role in EMT as well as the processes of metastasis and chemoresistance [10, 11]. TTK expression has been reported to be strongly elevated in EC tissues and high TTK expression was

associated with significantly poor prognosis [12]. In addition, an interesting paper yielded similar results as we did. A recent study discovered that inhibition of TTK expression significantly suppressed the proliferation of EC cells [13]. Similar to these previous studies, our findings suggested that TTK plays a critical role in EC cell proliferation, EMT, and TX resistance. Overall, we demonstrated that inhibiting TTK may prevent EC metastasis and chemotherapy (Fig. 9).

We investigated the link between dysregulated CTA gene levels and EC patient prognosis. According to our data, dysregulated CTAs scores in EC correlated with higher tumor stage and lower overall survival. *TTK* was also discovered to be highly expressed in the CTA^{high} group, and the expression of this gene was significantly associated with lower survival. In addition, despite the great progress in understanding molecular tumor processes throughout the years, there are still no biomarkers routinely used to detect EC early. In this study, mRNA levels of *TTK* were greatly increased in early-stage EC compared to the benign tissues. Furthermore, our ROC analysis revealed that *TTK* was extremely accurate in distinguishing stage I EC tissues

from benign endometrial samples, suggesting that TTK might be a biomarker for the early detection of EC.

Through WGCNA analysis and GSEA enrichment analysis of transcriptome data from EC samples in TCGA, we found that TTK in EC samples mainly regulates the cell cycle by regulating mitotic checkpoints, thus promoting tumor progression. In addition, we explored the reasons for the shortened survival of EC caused by TTK dysregulation in EC samples at the mutational, CNV, and epigenetic levels, respectively. Our analysis confirmed that higher TTK expression was more frequently detected in the poorly differentiated tumors, advanced stage of disease, *TP53*-mutated, and serous ECs. Thus, this study also suggests that TTK might be employed to predict EC development and metastasis.

Recent applications of single-cell transcriptome analysis in gynecological cancers include elucidating the heterogeneity of the disease, collecting micro-environmental data, elucidating drug resistance mechanisms, and enhancing cancer diagnostic and treatment approaches [46]. Previous research found that EC cells could be classified into several cell types: epithelial cells, fibroblasts, immune cells, and endothelial cells [47]. However, an in-depth analysis of epithelial EC cells at the single-cell level is currently lacking. Here, by studying the transcriptomes of single cells, we discovered the intra-tumor heterogeneity of EC and demonstrated that EC is comprised of different cell types (epithelial cells, immune cells, fibroblasts, and endothelial cells). In addition, we uncover a rare cluster of EC cells with proliferative signatures. Interestingly, we showed that *TTK*, hub genes, and EMT-associated genes were enriched in this proliferative subpopulation, implying that these cells tend to have more aggressive behavior. Our transcriptomic analysis also revealed that genes highly expressed in proliferative cells are more often expressed by serous ECs, rather than EEC tumors. In line with our findings, Olbrecht et al. recognized a molecular subtype of ovarian cancers based on single-cell RNA sequencing data and they reported that tumor sub-clusters expressing proliferative genes were enriched for EMT, hypoxia, and hedgehog signaling, all of which contribute to the greater aggressiveness of ovarian cancer [48]. These results support that a subpopulation of EC cells with proliferative capability may be responsible for accelerated metastatic development and TTK overexpression may be a valuable biomarker for predicting a highly aggressive nature.

A phenomenon called partial EMT or hybrid EMT, in which epithelial cancer cells display both mesenchymal and epithelial features, has been reported [49, 50]. Previous research has shown that partial EMT is more common in ECs than complete EMT [51]. Based on single-cell data from EC samples in the GEO database, we

identified a subpopulation of proliferating malignant epithelial cells in EC that increases with tumor malignancy. The upregulation of *TTK* and numerous EMT-related genes was detected in proliferative cells, indicating that this subpopulation retains high proliferative potentials, while undergoing an EMT program. When proliferative cells were categorized according to their *TTK* expression levels, we discovered that the overexpressed genes in the *TTK*^{high} group were functionally engaged in regulating chemoresistance. These results collectively supported the notion that activation of TTK and its downstream pathways might contribute to the proliferation, EMT features, and chemoresistance of EC cells. In line with this possibility, cell functional experiments have proven that silencing TTK with shRNA significantly attenuated the proliferative and invasive properties and abolished the resistance to the anti-cancer drug TX. Animal models would be required in the future to demonstrate whether TTK silencing or specific inhibition may prevent EC metastasis and boost chemotherapeutic effectiveness.

Typically, TTK and other cancer-testis antigens are expressed in testicular and tumor but not in normal [7–11]. TTK has been implicated in the activation of EMT in breast [10] and bladder cancers [38]. In the current investigation, we found that TTK promotes EMT in EC cells by increasing the expression of EMT inducers (*EZH2* and *BMI-1*) and decreasing the expression of the epithelial marker *CK-18*. These results imply that reducing TTK expression could potentially be developed as a new strategy to specifically inhibit the metastasis of EC. The mechanism by which TTK enhances EC aggressiveness and chemoresistance through *EZH2* overexpression remains to be determined.

Prior studies have shown that ECs with high levels of miR-21 expression had advanced tumor stages, high histological grades, cervical invasion, myometrial invasion, and distant metastasis [52]. As a result, miR-21 might be used as a biomarker to identify benign lesions from ECs [52]. MiR-21 has been shown to promote the growth of esophageal carcinoma [53], melanoma [54], and cervical cancer [55]. MiR-21 promotes EMT in renal cell cancer [56]. MiR-21 confers doxorubicin resistance in gastric cancer [57]. In accordance with these results, we demonstrated that miR-21 overexpression was responsible for EMT development and TX resistance, suggesting that miR-21 inhibitors may be useful in increasing chemotherapeutic effectiveness in EC patients.

The mechanisms behind miR-21 overexpression in tumor cells have been reported [58, 59]. The oncogene *RAS* has been associated with miR-21 overexpression in a thyroid cell line generated from the thyroid gland [58]. In addition, *EZH2* increases miR-21 levels in glioma cells by epigenetically inhibiting the expression of a long

non-coding RNA called MEG3 [59]. MEG3 decreased miR-21 levels in chronic myeloid leukemia cells [60]. Our findings showed that TTK promotes EZH2 expression and causes miR-21 to be upregulated. Thus, TTK may activate the miR-21-dependent signaling pathway through EZH2. Notably, miR-21 has been shown to increase EZH2 expression in human lung cancer stem cells [61]. Therefore, when EZH2 and miR-21 work together, they may create a double-positive feedback loop that mediates the oncogenic activities of TTK and enhances EC aggressiveness and chemoresistance. However, further experimental verification is needed.

Numerous small-molecule drugs that suppress TTK activity have been discovered or created so far [62–65]. The selective TTK inhibitor CFI-402257 has anti-cancer effects on human colon cancer cells, causing cell death [62]. A TTK-targeting small drug (compound 13) dramatically suppressed breast cancer development in nude mice [63]. According to some research, combining TTK inhibitors with chemotherapeutic drugs may significantly boost the effectiveness of destroying tumor cells [64]. BAY-1217389 and CFI-402257, two selective TTK inhibitors, greatly decreased glioblastoma multiforme cell proliferation and enhanced the growth-suppressive efficacy of temozolomide [64]. Moreover, Mps1-IN-3, a selective small molecule TTK inhibitor, produced mitotic aberrations in glioblastoma cells, and its combination with vincristine increased cell death [65]. Apart from these reports, Multiple breast cancer cell lines with a basal-like phenotype were more radiosensitive after TTK inhibition by B909 [66]. In line with recent findings from EC, which demonstrated that a TTK inhibitor (NTRC0066-0) significantly reduced the growth of EC cells [13], we confirmed that pharmacological inhibition of TTK with AZ3146 decreased the proliferation and invasion of EC in vitro, and had a synergistic effect on the TX-induced apoptosis of EC cells. Therefore, TTK inhibitors could be used with existing anti-tumor drugs or radiation therapy to enhance tumor destruction. The future use of AZ3146 in conjunction with TX may improve the therapeutic benefits of TX in EC patients exhibiting high TTK expression (Fig. 9).

Conclusions

In summary, TTK was discovered as a new EMT activator for EC based on integrative multi-omics analysis and functional validation. TTK has the potential to be a valuable biomarker for the diagnosis of EC, the assessment of prognosis, and the prediction of chemoresistance (Fig. 9). Therefore, this study deepens our understanding of the biological function of TTK in EC and may provide new clues for treating this disease.

Expression of specific genes in EC. **Figure S2.** Differences in SMG and CNV associated with dysregulated TTK gene expression in EC. **Figure S3.** Extensive genomic changes of *TTK* gene in human cancers. **Figure S4.** Epigenetic differences associated with TTK dysregulation in EC. **Figure S5.** EMT-related genes expression across major cell types. **Figure S6.** Pharmacologic inhibition of TTK mimicked the effects of TTK silencing on EC cells.

Acknowledgements

We appreciate China National GeneBank and the technical assistance from Dr. Zhujie Xu.

Author contributions

Conception and design of the study: MF, PD and JY. Acquisition of data and data analysis: YM, BW and MF. Experimental investigation: YK and PD. Data interpretation: YM, YK, BW, PD, TZ, KI, NK, HW, JY, LZ and XJ. Drafting of the manuscript: PD, YM and MF. All authors read and approved the final manuscript.

Funding

This work was supported by a grant from JSPS Grant-in-Aid for Scientific Research (C) (22K09541 and 22K09634).

Availability of data and materials

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request. The public datasets analyzed during the current study are available in the repositories listed below: Gene Expression Omnibus: <https://www.ncbi.nlm.nih.gov/geo/>. The Cancer Genome Atlas: <http://cancergenome.nih.gov/>.

Declarations

Ethics approval and consent to participate

Not applicable.

Consent for publication

All of the authors are aware of and agree with the content of the paper and they are listed as co-authors of the paper.

Competing interests

The authors declare that they have no competing interests.

Publisher's Note

Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.

Ready to submit your research? Choose BMC and benefit from:

- fast, convenient online submission
- thorough peer review by experienced researchers in your field
- rapid publication on acceptance
- support for research data, including large and complex data types
- gold Open Access which fosters wider collaboration and increased citations
- maximum visibility for your research: over 100M website views per year

At BMC, research is always in progress.
