Short communications

1

Canine hemangiosarcoma (HSA), a highly fatal mesenchymal tumor of dogs, originates 12 from the endothelial cells lining of blood vessels. It is characterized by a short survival time with 13 14 a mean survival time of only 4 months. Recently, one study showed that histone lysine demethylase 2B (KDM2B) was highly expressed in canine HSA and was important in HSA 15 tumor cell survival by positively regulating DNA repair mechanisms. KDM2B has been reported 16 17 to be related to disease progression and patient survival in several human cancers. Thus, in this study, we studied the relationship of KDM2B expression levels with several patient clinical 18 profiles to investigate the role of KDM2B in clinical HSA tumors. We analyzed 37 canine HSA 19 cases and found that KDM2B is highly expressed in stage 3 HSA compared to stage 1 HSA. 20 High KDM2B expression was also found in male dogs compared to female dogs. No correlation 21

22	was observed between KDM2B expression and age. Classifying HSA patients into high and low
23	KDM2B expression groups revealed that the high KDM2B group showed shorter overall
24	survival than the low KDM2B group. Based on these results, we suggest that KDM2B
25	expression is associated with disease progression in HSA.

30	Text
31	Canine hemangiosarcoma (HSA) is the most common mesenchymal tumor in dogs. ¹ It
32	arises from vascular endothelial cells (EC) and is characterized by high rates of recurrence and
33	metastasis. ² Patients with HSA have short survival times with a mean survival time of only 4
34	months and fewer than 10% of dogs survive a year after initial diagnosis. ^{3,4} It usually develops
35	from the spleen, liver, heart, and skin. ⁵ It has been documented in several species including mice,
36	horses, cows, and humans. ^{6,7} At present, due to lack of a viable prognostic marker, clinical
37	staging is used to assess patient survival. A recent study found that lysine demethylase 2B
38	(KDM2B) highly expressed in canine HSA and played an important role in HSA tumor cell
39	survival by positively regulating DNA repair mechanisms.8 KDM2B has been reported to be an
40	oncogene in a variety of human cancers. ^{9–17} It promotes disease progression in pancreatic cancer
41	and ovarian cancer, and its expression levels were positively correlated to poor patient prognosis
42	in gliomas and breast cancers. ¹⁸⁻²¹ Based on these findings, we speculated that KDM2B was also
43	corelated to HSA malignancy like other human cancers. Therefore, in this study, we aimed to

investigate the relationships between KDM2B expression levels and disease progression or
patients' prognosis in HSA.

46 Clinical information on HSA cases was obtained from the archives of two veterinary pathology laboratories. Only HSA patients from 2010 to 2019, which were histologically 47 diagnosed by at least 3 certified veterinary pathologists, were included. Samples, which 48 49 consisted of tumor biopsies after splenectomy or the tumor with major organs at necropsy, were collected from patients and fixed in 10% neutral buffered formalin. The samples were then cut, 50 51 embedded in paraffin, sectioned, and stained with hematoxylin and eosin according to standard protocols. Immunohistochemistry with anti-KDM2B antibody (sc-293279, Santa Cruz 52 Biotechnology, Dallas, TX) was performed as previously described.⁸ Briefly, paraffin-embedded 53 tissue sections were deparaffinized, rehydrated, and then heated in 10 mM EDTA pH 8.0 buffer 54 for 15 mins in a microwave to retrieve antigens. Endogenous peroxidase activities were 55 quenched with 0.3% H₂O₂ in methanol. Tissue sections were blocked with 10% normal rabbit 56 57 serum (Nichirei biosciences, Tokyo, Japan) for an hour at room temperature (RT). The tissue sections were then washed and incubated with anti-KDM2B antibody (1:50) or PBS (for 58 negative control) overnight at 4°C. Chromogenic detection was performed by incubating with 59 60 simple stain mouse MAX-PO (Nichirei biosciences, Tokyo, Japan) for an hour at RT, followed by addition of HRP-conjugated streptavidin solution and 3-3'-diaminobenzidine (DAB; Dojindo, 61 62 Kumamoto, Japan). The slides were scanned with Nano Zoomer 2.0-RS (Hamamatsu Photonics, 63 Hamamatsu, Japan) and then KDM2B DAB Max intensity of tumor cells and EC was measured with QuPath ver. 0.2.1.²² KDM2B expression levels in tumor cells were normalized by that in 64 EC on the same slide. Normalized KDM2B expression levels were used for further analysis as 65 the KDM2B ratio. The R software (version 3.6.3) was used to perform statistical analysis. 66

Shapiro-Wilk test was used to check the normality of variables distribution. When the values are
normally distributed, Student's *t*-test or Tukey's test were used. When the values are not
normally distributed, Mann-Whitney U test was performed. Disease-free survival (DFS) was
defined as the time between surgery and detection of tumor metastases or death. Overall survival
(OS) was defined as the time between surgery and death. DFS and OS were analyzed with the
Cox regression analysis or the Log-rank test.

73 A total of 37 cases were included in this study. Detail information is summarized in Table 74 1. The median and average age of the patients at the time of diagnosis were 10 and 10.4 years, respectively (range: 5-14 years). The study population consisted of twenty male and seventeen 75 female dogs, some of which were neutered. The most common breed was miniature dachshund, 76 77 followed by retriever breeds and miniature schnauzer. HSA developed in the spleen in almost 80% cases (29/37 cases), while there were only one or two cases each in other sites. Most 78 79 metastases were observed in the liver (8/37 cases) and the lung (6/37 cases). The medians of DFS and OS were 87.5 and 125 days, respectively (both DFS and OS ranges were 4-926 days). 80 The average KDM2B ratio was 1.49 while the median KDM2B ratio was 1.31 (range: 0.55-81 3.10). 82

We first performed the Cox regression analysis to evaluate the relationship between KDM2B ratio and DFS or OS (Table 2). There was no correlation between KDM2B ratio and DFS or OS (P = 0.2443 and P = 0.2692, respectively). KDM2B ratio was also not correlated with age (r = -0.0529) (Fig. 1). Next, to investigate the correlation of KDM2B ratio with disease progression, we classified HSA patients into three clinical stages. HSA patients with tumors confined to the primary organ were classified under clinical stage 1, patients with ruptured primary HSA or patients with tumor spread to draining and regional lymph nodes were classified

under clinical stage 2, and HSA patients with distant metastases were classified under clinical 90 stage 3.²³ Since only one case was classified into stage 2, we compared KDM2B ratio between 91 stage 1 and stage 3. The results indicated that KDM2B ratio was significantly high in patients 92 under clinical stage 3 compared to patients in stage 1 (Fig. 2A). The number of metastatic sites 93 was not correlated with KDM2B ratio (Fig. 2B). We also compared KDM2B ratio with sex and 94 95 found that it was significantly higher in males than in females (Fig. 2C). These results suggest that the KDM2B expression is correlated with disease progression and may be influenced by 96 97 gender.

Although KDM2B ratio was higher in clinical stage 3, the Cox regression analysis did 98 not detect correlation between KDM2B ratio and DFS or OS. To further investigate the 99 100 association of KDM2B expression with clinical outcomes, each dog was classified into high 101 KDM2B or low KDM2B group based on the optimal threshold (KDM2B ratio = 1.16) determined by using X-tile software ver. 3.6.1 (Yale School of Medicine, CT, USA).²⁴ The DFS 102 of the high KDM2B group (median DFS: 50 days) was likely to be shorter than that of the low 103 KDM2B group (median DFS: 176.5 days) (P = 0.06; Fig. 3A). The OS of the high KDM2B 104 group (median OS: 52 days) was significantly shorter than that of the low KDM2B group 105 (median OS: 188 days) (P = 0.02; Fig. 3B). These results suggest that KDM2B expression might 106 be related to the patients' prognosis. 107

In the present study, we found that KDM2B expression was correlated to disease progression in HSA. Furthermore, although the sample size was small, the patients classified in high KDM2B group showed the shorter overall survival time than in low KDM2B group. These results suggest that KDM2B is associated with HSA malignancy. KDM2B has been reported to promote disease progression in cooperation with the histone methyltransferase EZH2.^{13,25} A previous study showed that KDM2B and EZH2 were both upregulated in HSA cell lines

114 compared to the normal canine endothelial cells,⁸ suggesting that KDM2B and EZH2 might

115 work together in HSA. Since the role of EZH2 in HSA has not yet been studied, investigating

116 KDM2B and EZH2 functions would be beneficial to understand HSA pathogenesis.

Given that the clinical staging that we used in this study was mainly based on metastatic 117 118 status, KDM2B might be able to make HSA tumor cells more metastatic like in other cancers.^{12,26} Metastasis is one of the major factors causing hypovolemia leading to death in HSA 119 patients.²⁷ However, in this study, the Cox regression analysis did not find correlation between 120 121 KDM2B ratio and DFS or OS even though classifying patients based on KDM2B ratio revealed statistically significant difference in OS. This is probably because of the small sample size. To 122 prove whether KDM2B promotes metastatic ability and contributes to patient survival in HSA, 123 124 further research with an increased sample size is necessary.

We also found a difference in KDM2B expression in male and female patients. In a previous case-control study in HSA, males were found to be more likely to develop HSA than females.²⁸ However, another research reported that there was no sex predisposition in HSA.^{3,7} Thus, it is still unclear that the high KDM2B expression in males observed in this study is related to HSA tumorigenesis. To address this question, further studies are required that focuses on KDM2B and sex prediction.

In conclusion, we showed the KDM2B expression is associated with HSA disease progression. To further elaborate how KDM2B contributes to HSA malignancy and whether its expression is associated with the prognosis of patients, additional research with the increased number of patients must be conducted.
