Supplementary Methods

Registry systems

Data from treatment decision sites (TDS) and registration centres for test-positive patients (RCPP) were utilized for analyses. The TDS is a system launched by the City of Sapporo to notify individuals with a COVID-19 diagnosis of the need for hospitalization and clinical advice. Individuals diagnosed with COVID-19 (see **Inclusion criteria** below for diagnostic methods for COVID-19) were requested to immediately register clinical information with the TDS through a web device, including the presence/absence of 12 preselected specific symptoms at the time of registration and the date of symptom onset. The RCPP is a registration system operated by the City of Sapporo for symptomatic individuals who cannot visit a healthcare provider. The RCPP sends SARS-CoV-2 antigen test kits to symptomatic individuals at home upon request. A self-test is conducted, and information identical to that for the TDS is entered into the RCPP system by test-positive individuals. Based on the registered information, a medical care policy was automatically developed and individuals notified. Individuals with a diagnosis of COVID-19 were provided with food delivery services and medical advice when the decision was made for home isolation. For those who were unable to provide care at home or at high risk, hospitalisation was arranged. The costs of diagnosis and treatment of COVID-19 were covered by public funds. Details of the two systems are also shown in **Fig. S1**.

Inclusion criteria

Individuals with COVID-19 who registered for the TDS or the RCPP website during the study periods were included in the study. Individuals residing in Sapporo were eligible to register for TDS if they met the following criteria: 1) symptomatic individuals who visited a medical institution and tested positive for SARS-CoV-2 (polymerase chain reaction or antigen test); and 2) individuals who were not tested for SARS-CoV-2 but developed new symptoms after a household member tested positive for SARS-CoV-2.

Exclusion criteria

- 1) Incorrect input value for the date of onset (later than the registration date).
- 2) Registration date is more than five days after the onset date.
- 3) Under the term "Symptoms to date", "Nothing" was selected. Applicable cases were treated as asymptomatic individuals and excluded.

We defined an acute phase of COVID-19 infection as a period of five days following symptom onset as previously reported¹, and included individuals who developed COVID-19 symptoms during the defined period. Individuals who registered in our registry system six or more days after symptom onset were excluded from the analysis.

Our registry system included some individuals who reported no symptoms. However, the TDS and RCPP were designed to provide clinical instructions for symptomatic individuals with COVID-19 infection and asymptomatic individuals with COVID-19 infection were not considered as a main target of the system. Thus, we excluded asymptomatic individuals with COVID-19 infection registered in the system from the study.

Definition of symptoms

Fever was defined as body temperature $\geq 38^{\circ}\text{C}$. Decreased food intake was defined as less than 30% of baseline food intake.

Definition of missing values and treatment

The missing values were applicable for age, sex, and body mass index (BMI). For age, values above 120 were determined to be erroneously entered and were considered missing values. Missing values were assigned to cases in which sex was unknown. A BMI of < 8 and > 70 were determined to be inappropriate values and considered as missing values. The number and percentage of cases in each category were calculated, excluding cases with missing values. Multivariable analysis was performed for cases without missing values.

Statistical analysis

We used the following formula to estimate the appropriate sample size:

$$n = Z^2 \times P \times (1 - P) / d^2.$$

- Z = value from standard normal distribution corresponding to desired confidence level (Z=1.96 for 95% confidence interval [CI])

- P = expected true proportion

- d = desired precision (half desired CI width)

In previous reports, the prevalence of COVID-19 symptoms ranged from 1-80%¹. In the present study, the 50% with the largest calculated estimated sample size was set as the prevalence, and a precision of 0.01 was used to calculate the optimal sample size with a confidence interval width of 1% for the 50% proportion, which was 9604. The sample size of our study exceeded the figure.

Continuous data were presented as medians (interquartile range) and categorical data were presented as numbers and percentages. A 95% CI for symptom prevalence, odds ratio (OR) and hazard ratio (HR) was calculated by the score method and Wald test, respectively.

Multivariable logistic regression analyses were performed, using days from symptom onset, age, sex, BMI, underlying diseases, SARS-CoV-2 omicron subvariant, vaccination status, and previous SARS-CoV-2 infection as explanatory variables, with the development of each symptom as the outcome. Considering that times for development of each symptom could vary after the first symptom onset, the number of days that passed since first symptom onset was treated as a categorical variable. Other variables have been reported as predictors of COVID-19 outcomes, and all variables that were available from the registry system were incorporated. Vaccination status was divided into two groups with more vs. less than three vaccinations as the boundary, a number clinically relevant to omicron variants. For two- and three-dose vaccinees, categories were created to account for the passage of time by dividing the number of days since last vaccination into 60-day intervals and incorporated into specific models. The number of individuals who received the single and four doses was small and they were excluded from the models. To test whether specific symptoms increased the odds of severe disease, a multivariable logistic regression analysis was performed. The objective variable was progression to severe disease, and 12 symptoms were used as explanatory variables along with the above variables.

Propensity score matching was performed using a 1:1 nearest available matching algorithm without replacement and a caliper of 0.05. The propensity score for

each variable was calculated by logistic regression analysis with the variables, including omicron subvariants, age, sex, obesity, underlying disease, vaccine status, including time since last vaccination, and previous SARS-CoV-2 infection. Absolute value of standardized difference greater than 0.1 was considered as a sign of imbalance.

To estimate symptom time courses, proportion of the 12 predefined symptoms were calculated from individuals aligned by days from first symptom onset and plotted on a day 0-5 scale (Table S7).

The estimation of HR of symptom accumulation was analysed using a multivariable Cox regression model, starting from day 0 as the symptom onset to day 5 as the end time. Built-in selection bias should be taken into account when estimating HR in observational study. However, it seems to have less influence in this study because the time period was not delimited, and the follow-up period was short (Table S8). We performed a proportional hazards assumption check using the graph of the log of the negative log of the estimated survivor functions against the log of time.

Spearman's correlation coefficient was calculated to test the strength of the correlation between the two symptoms (Figure S2).

We conducted a multivariable logistic regression analysis to investigate the changes in OR for progression to severe disease based on the number of systemic symptoms and upper respiratory symptoms. Ordinal variables were set for the number of systemic symptoms (fever, decreased food intake, severe fatigue, and dyspnea, 0-4) and the number of upper respiratory symptoms (sore throat and nasal discharge, 0-2), and they were incorporated along with the remaining six symptoms as explanatory variables (Table S12).

All statistical analyses were performed using JMP® Pro Version 16.2.0 and SAS® Version 9.4 (SAS Institute Inc., Cary, NC, USA).

*Excluded from analysis due to small number of symptomatic individuals for which confidence intervals could not be determined.

** “Sore throat” and “nasal discharge”

***“Fever”, “decreased food intake”, “severe fatigue”, and “dyspnea”

BMI, body mass index; CI, confidence interval; OR, odds ratio; SARS-CoV-2, severe acute respiratory syndrome coronavirus.

Figure S1

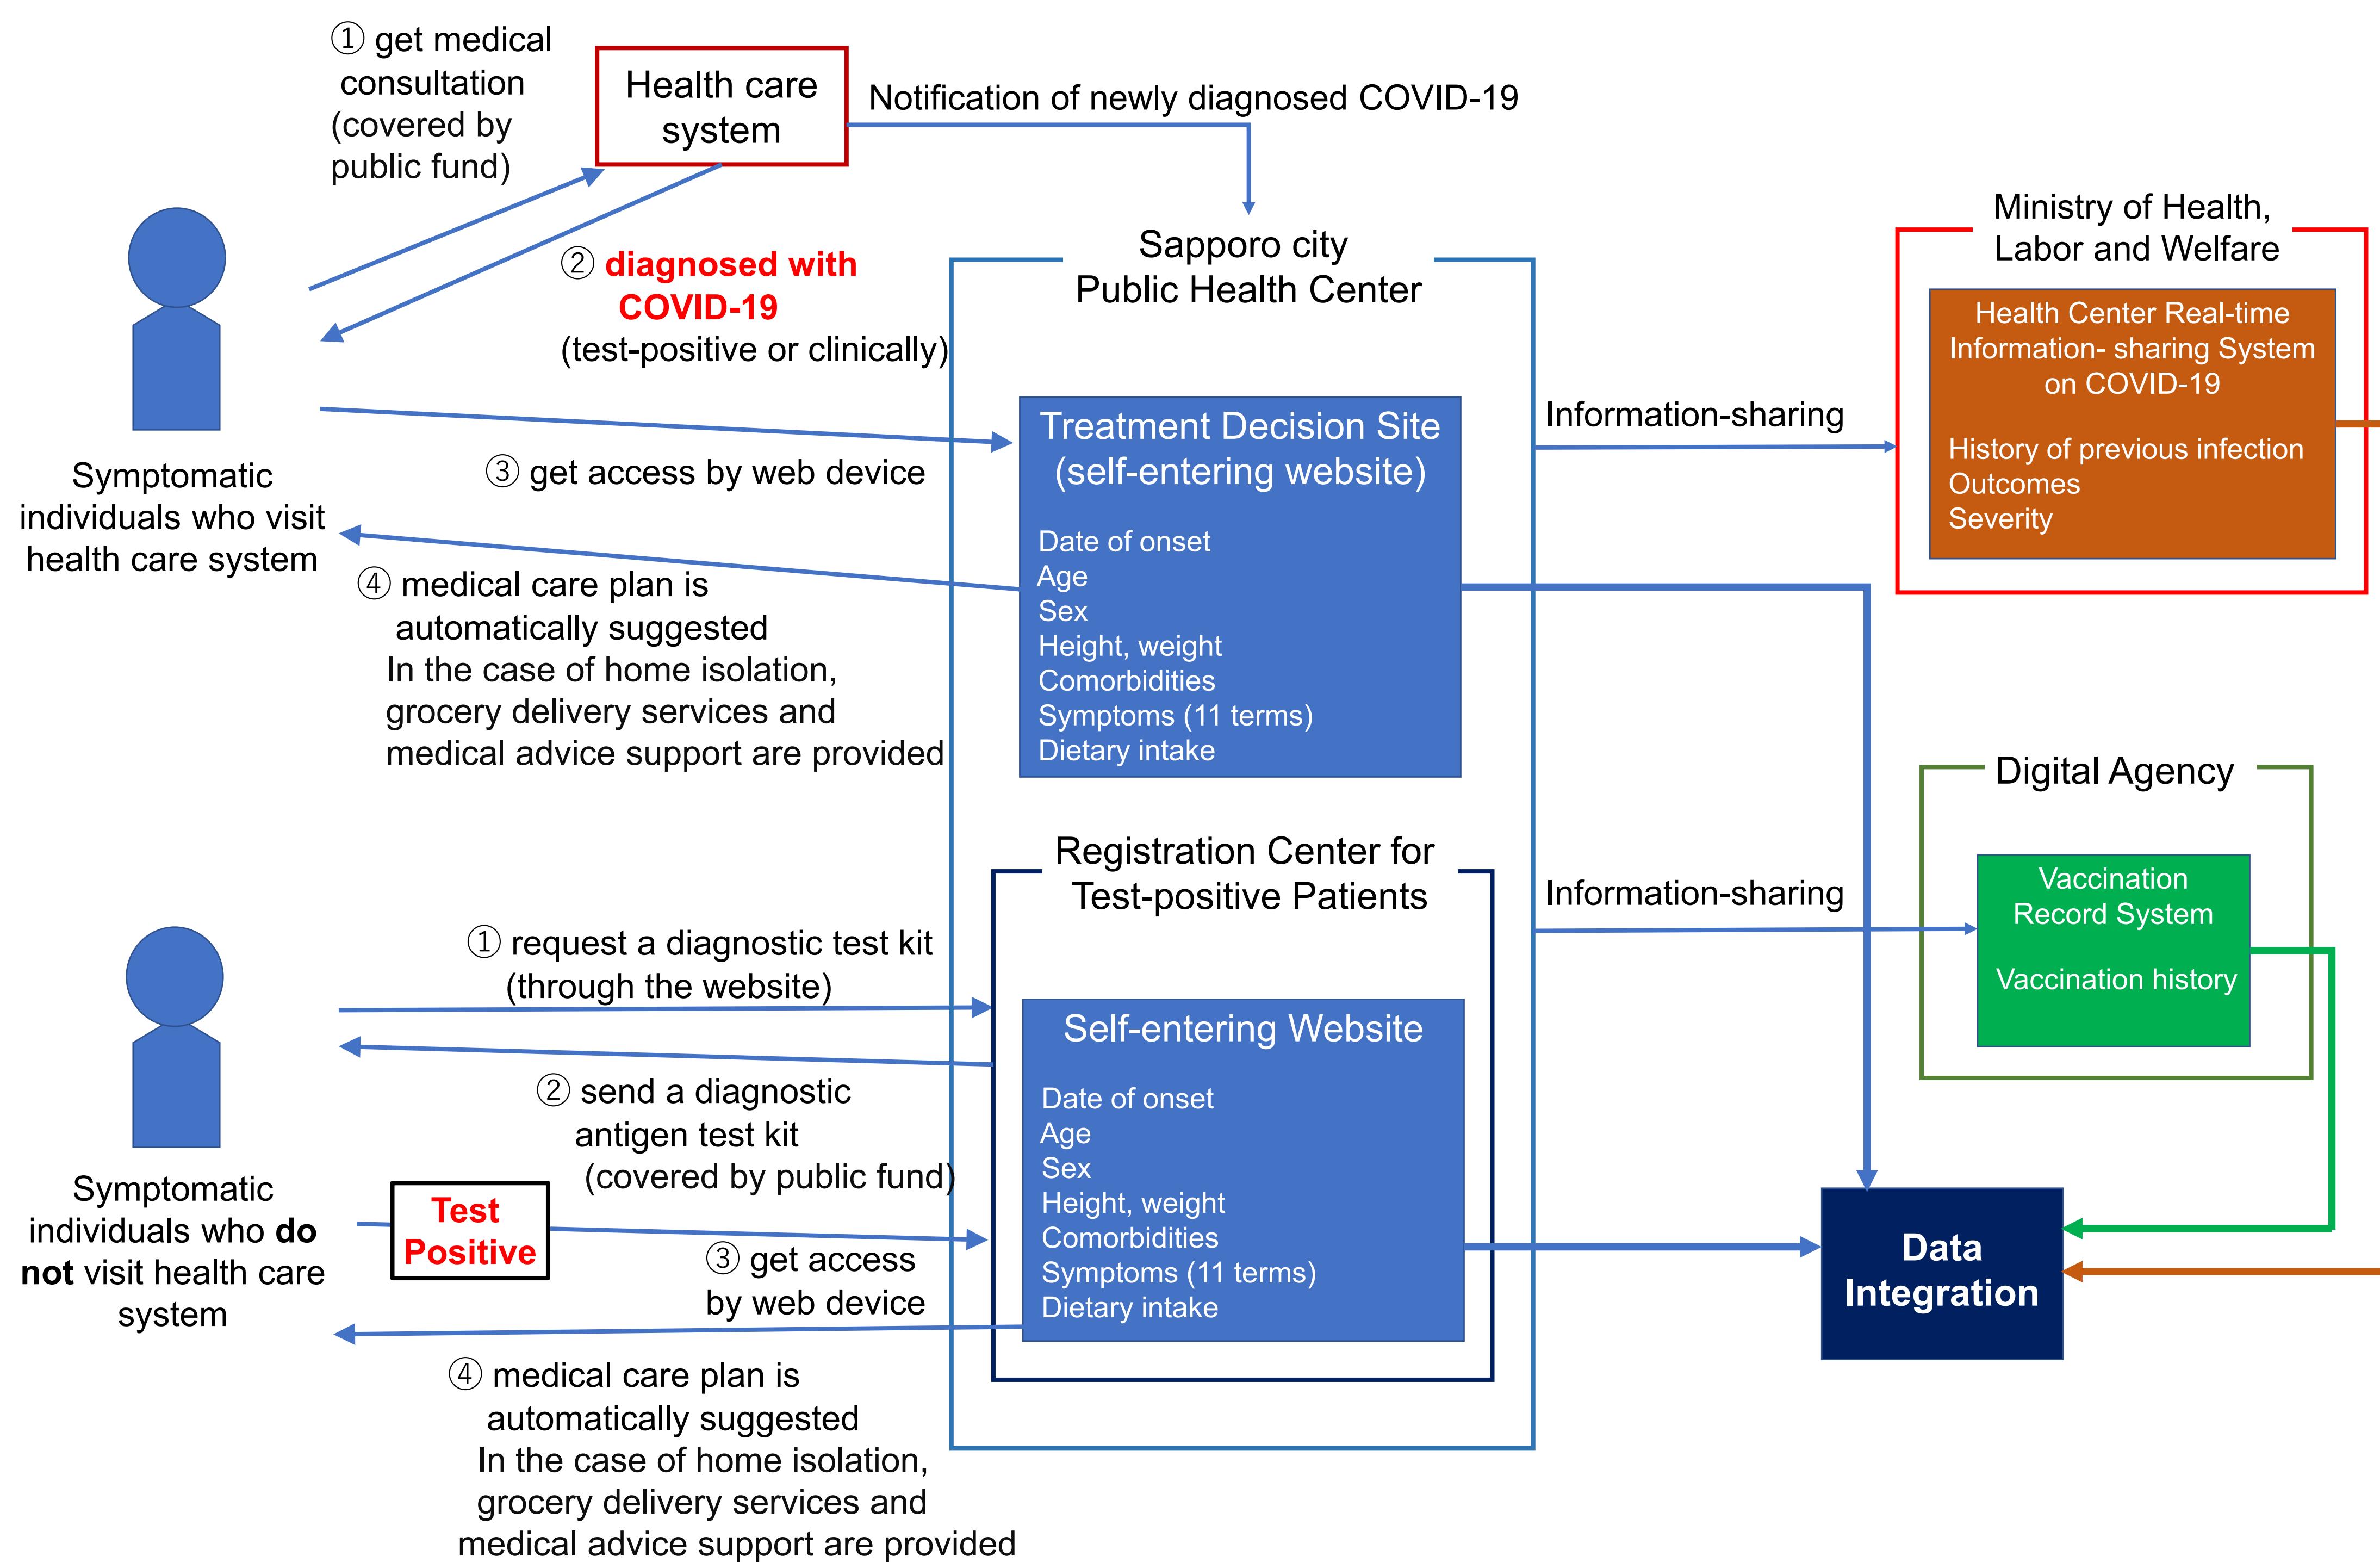

Figure S1. Schema of information registration system for symptomatic COVID-19 patients in Sapporo. Treatment Decision Site (TDS) is an online information registration system set up by Sapporo City Public Health Center. Registration Center for Test-positive Patients (RCPP) is a registration center operated by Sapporo City Public Health Center. The Ministry of Health, Labor and Welfare and Digital Agency are administrative agencies belonging to the Japanese government.

Figure S2

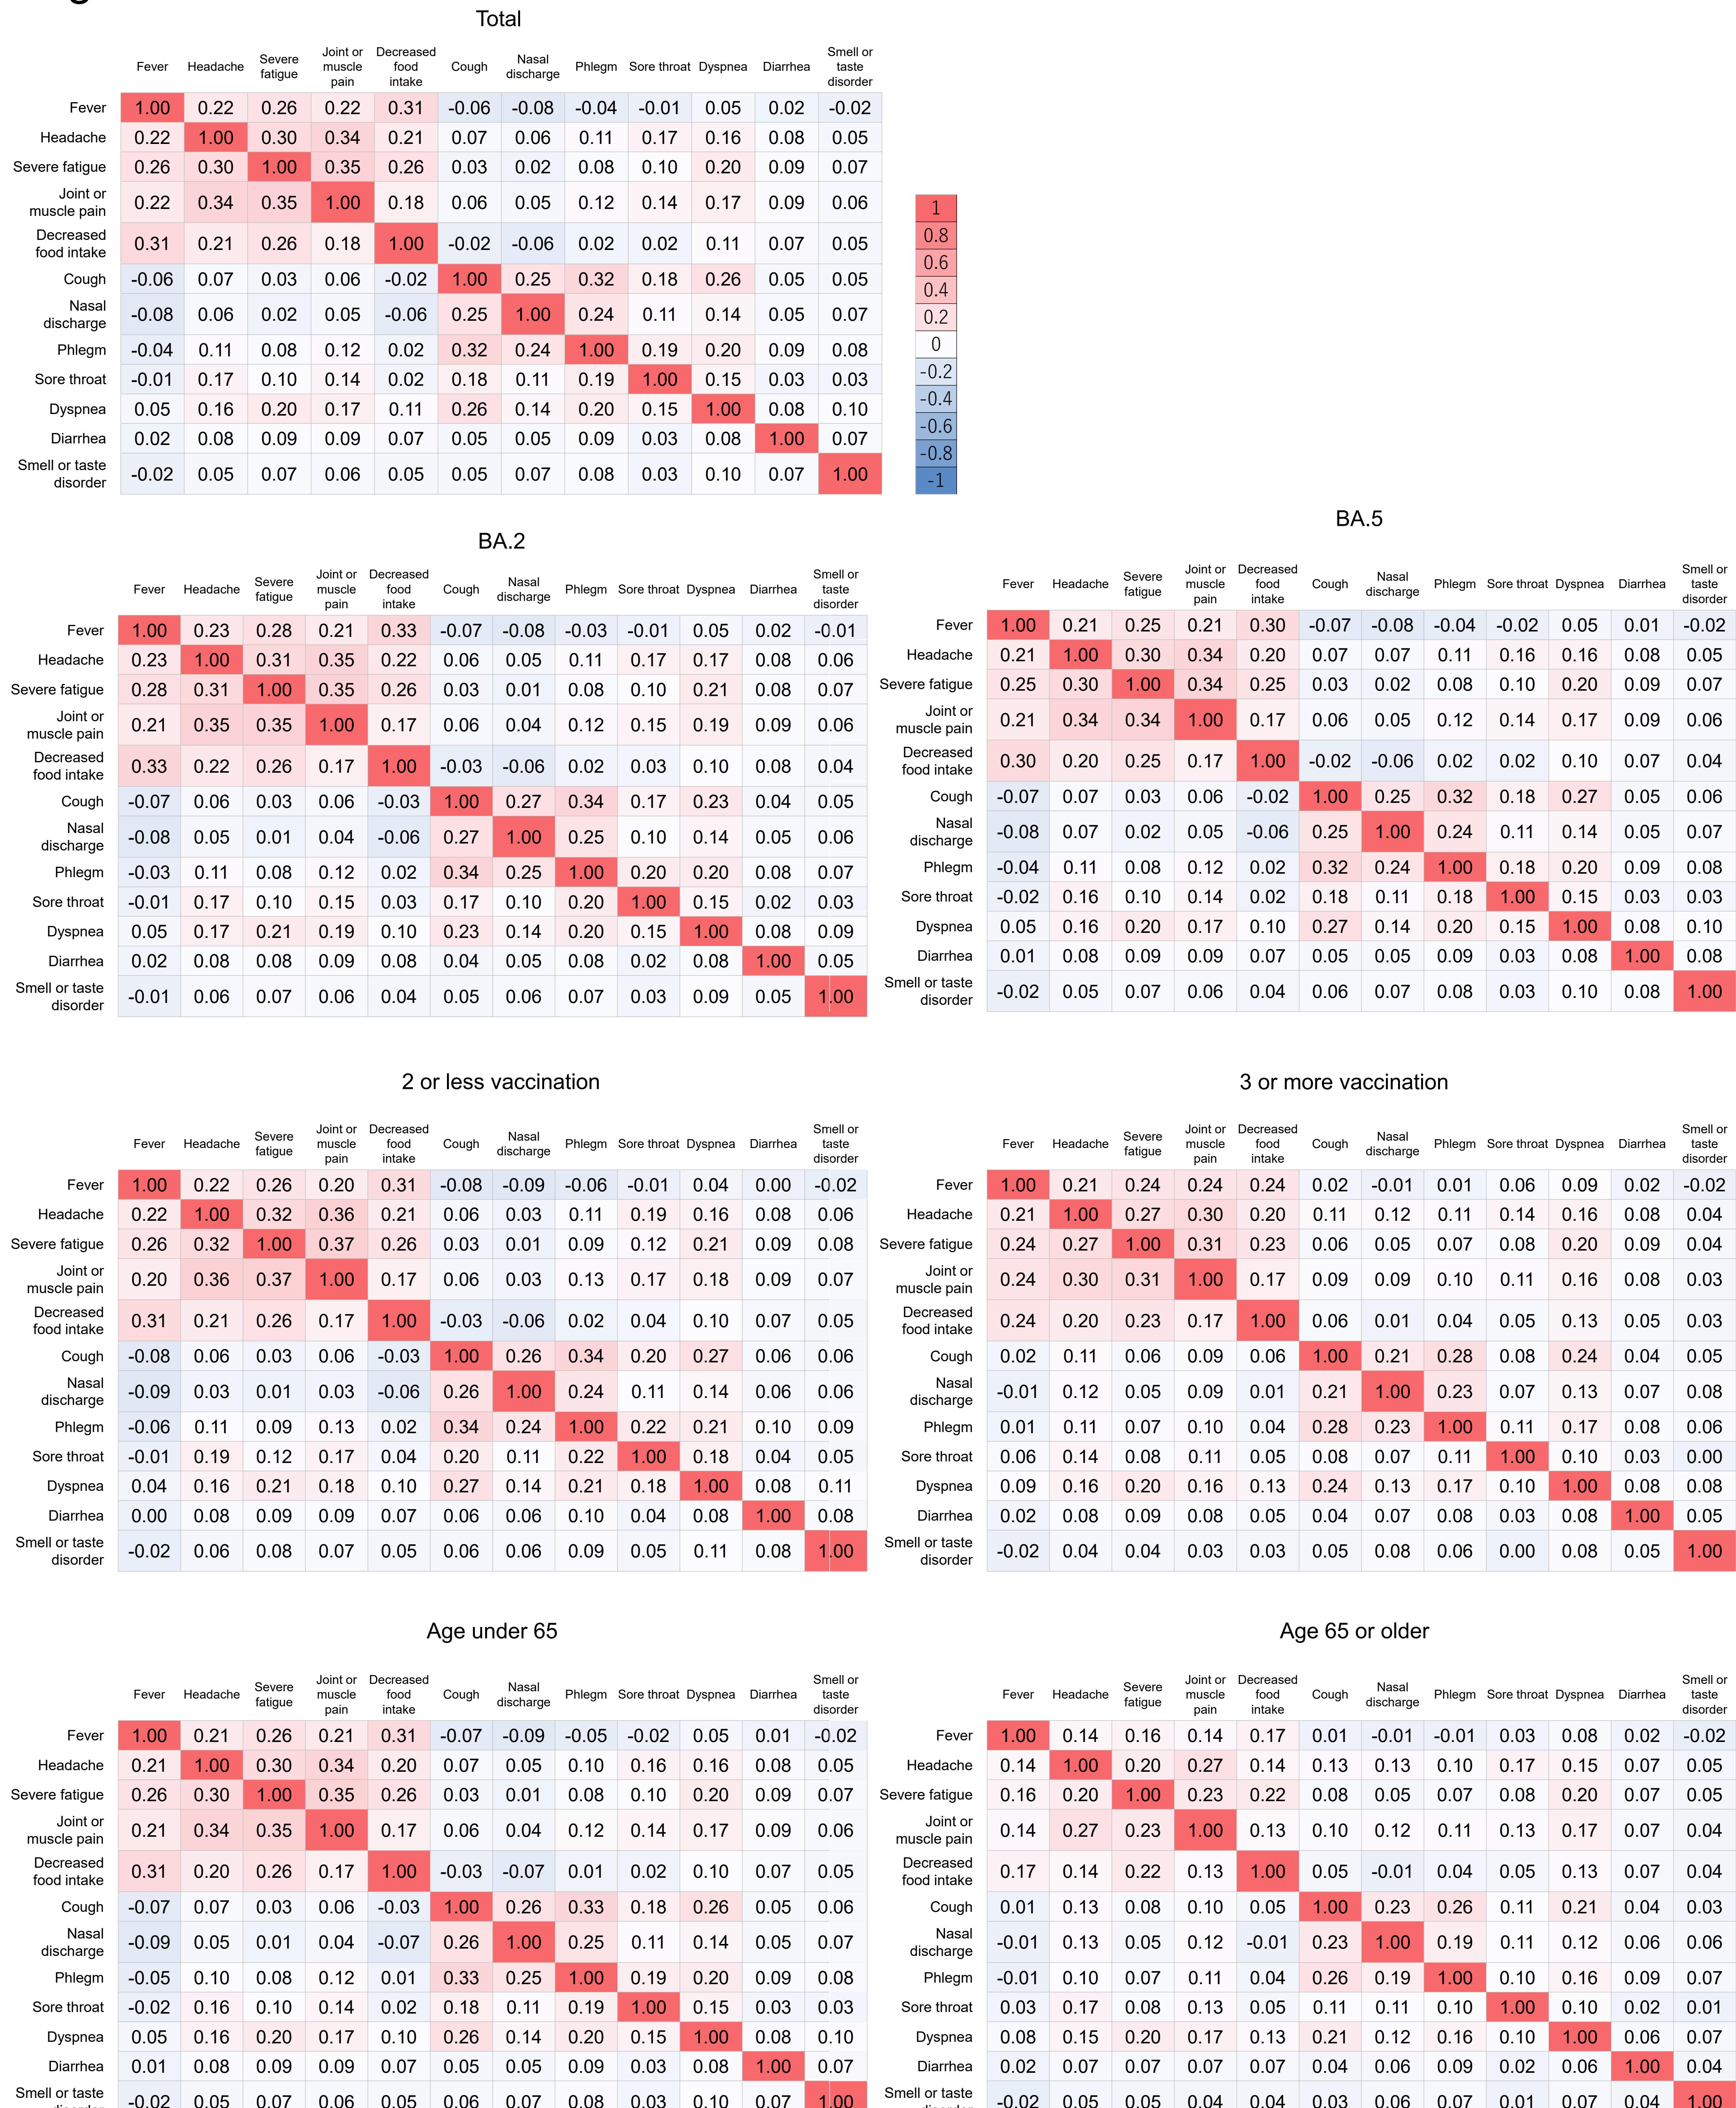

Figure S3

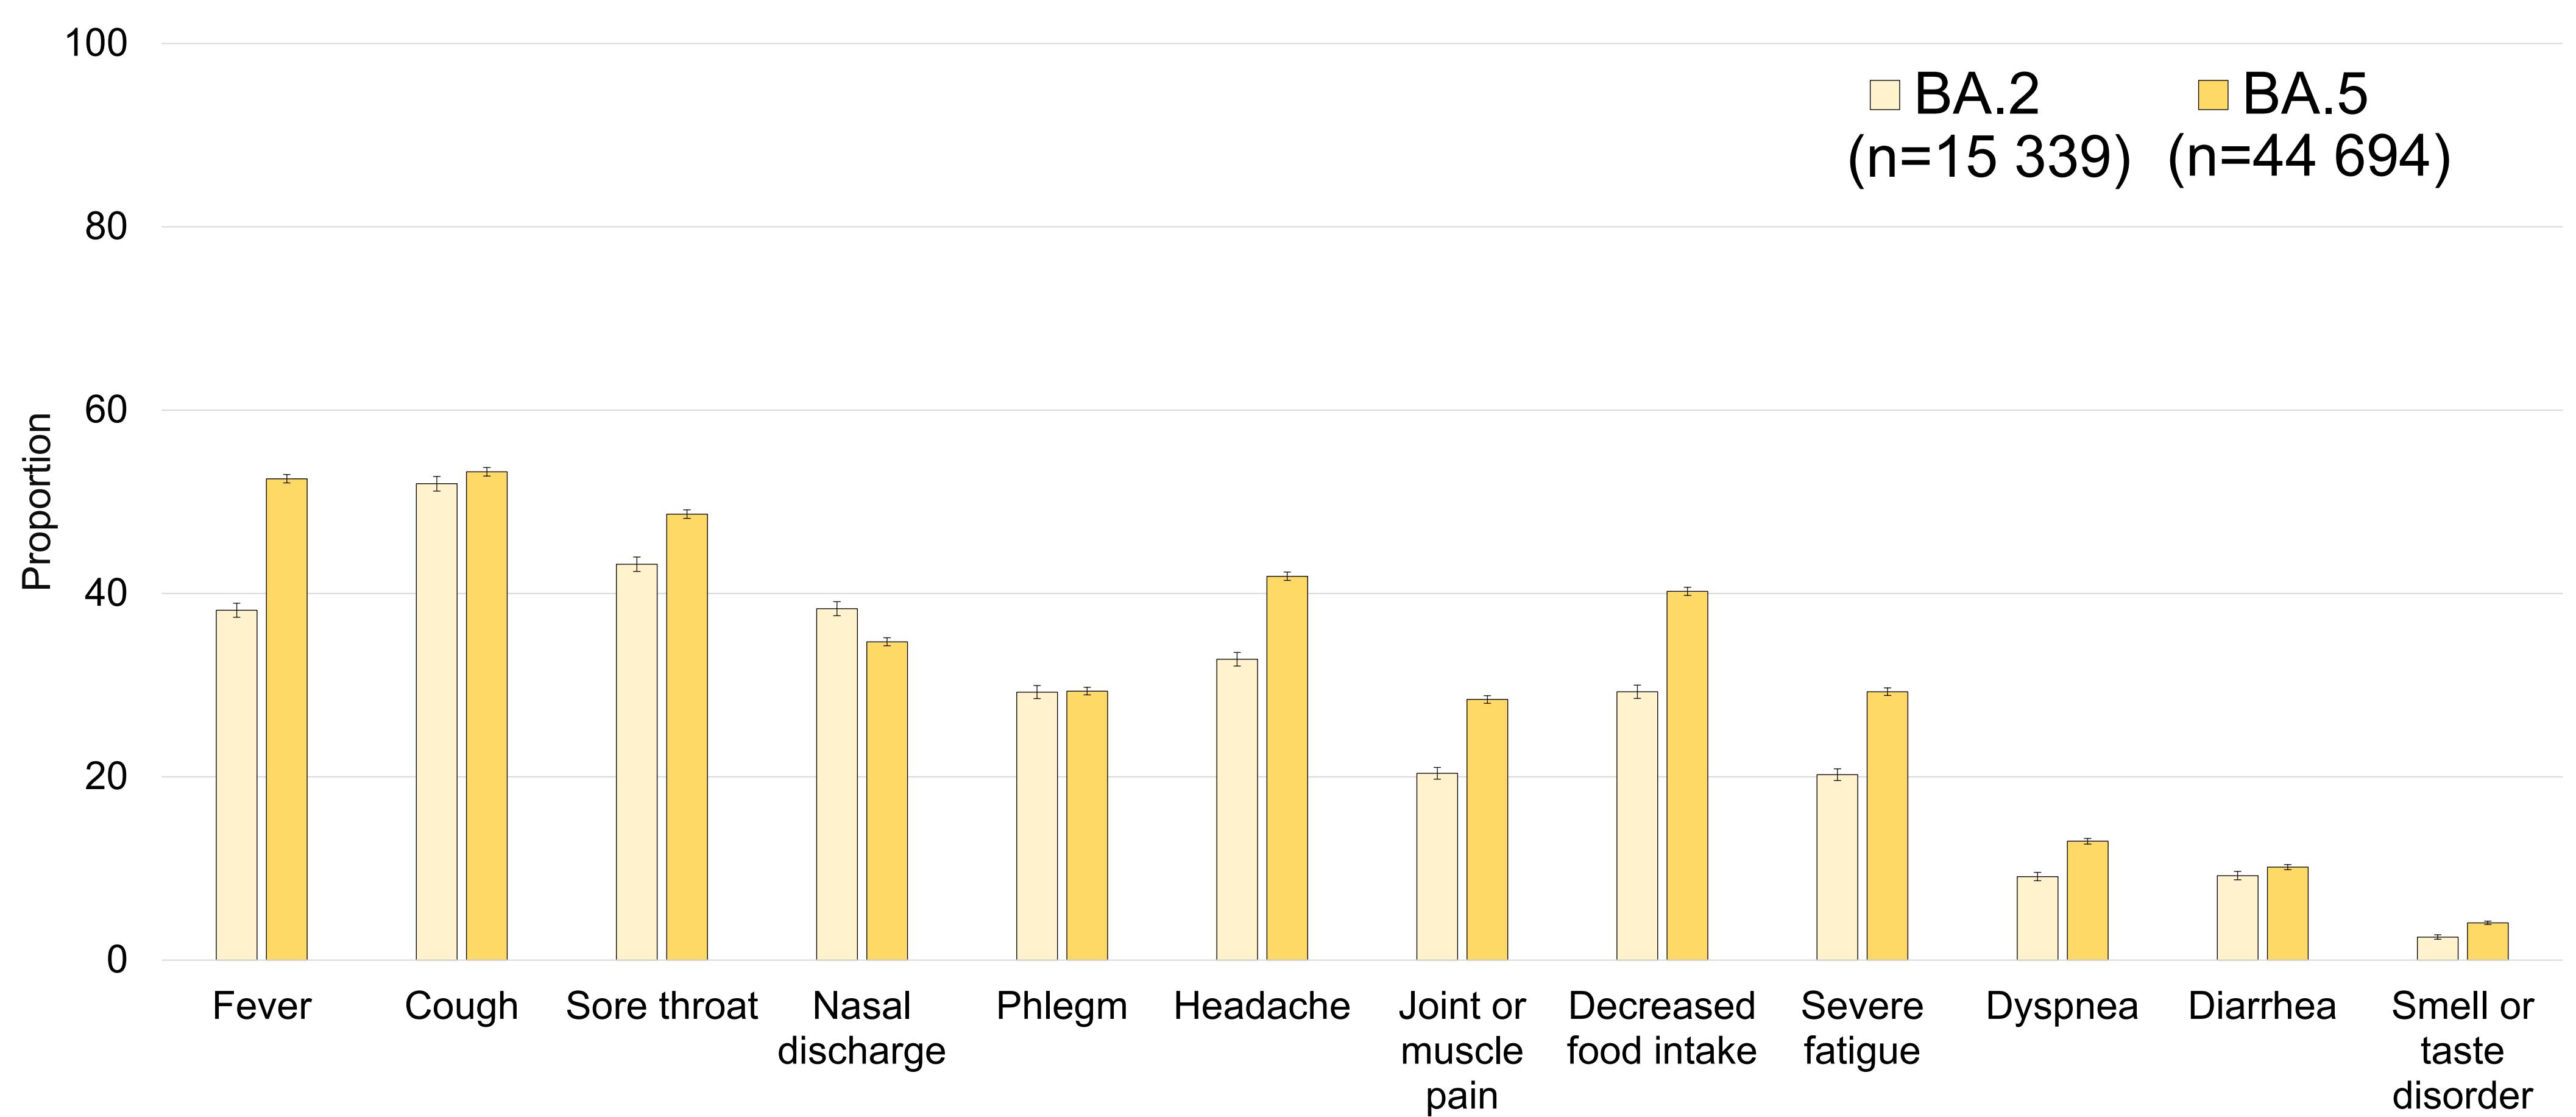

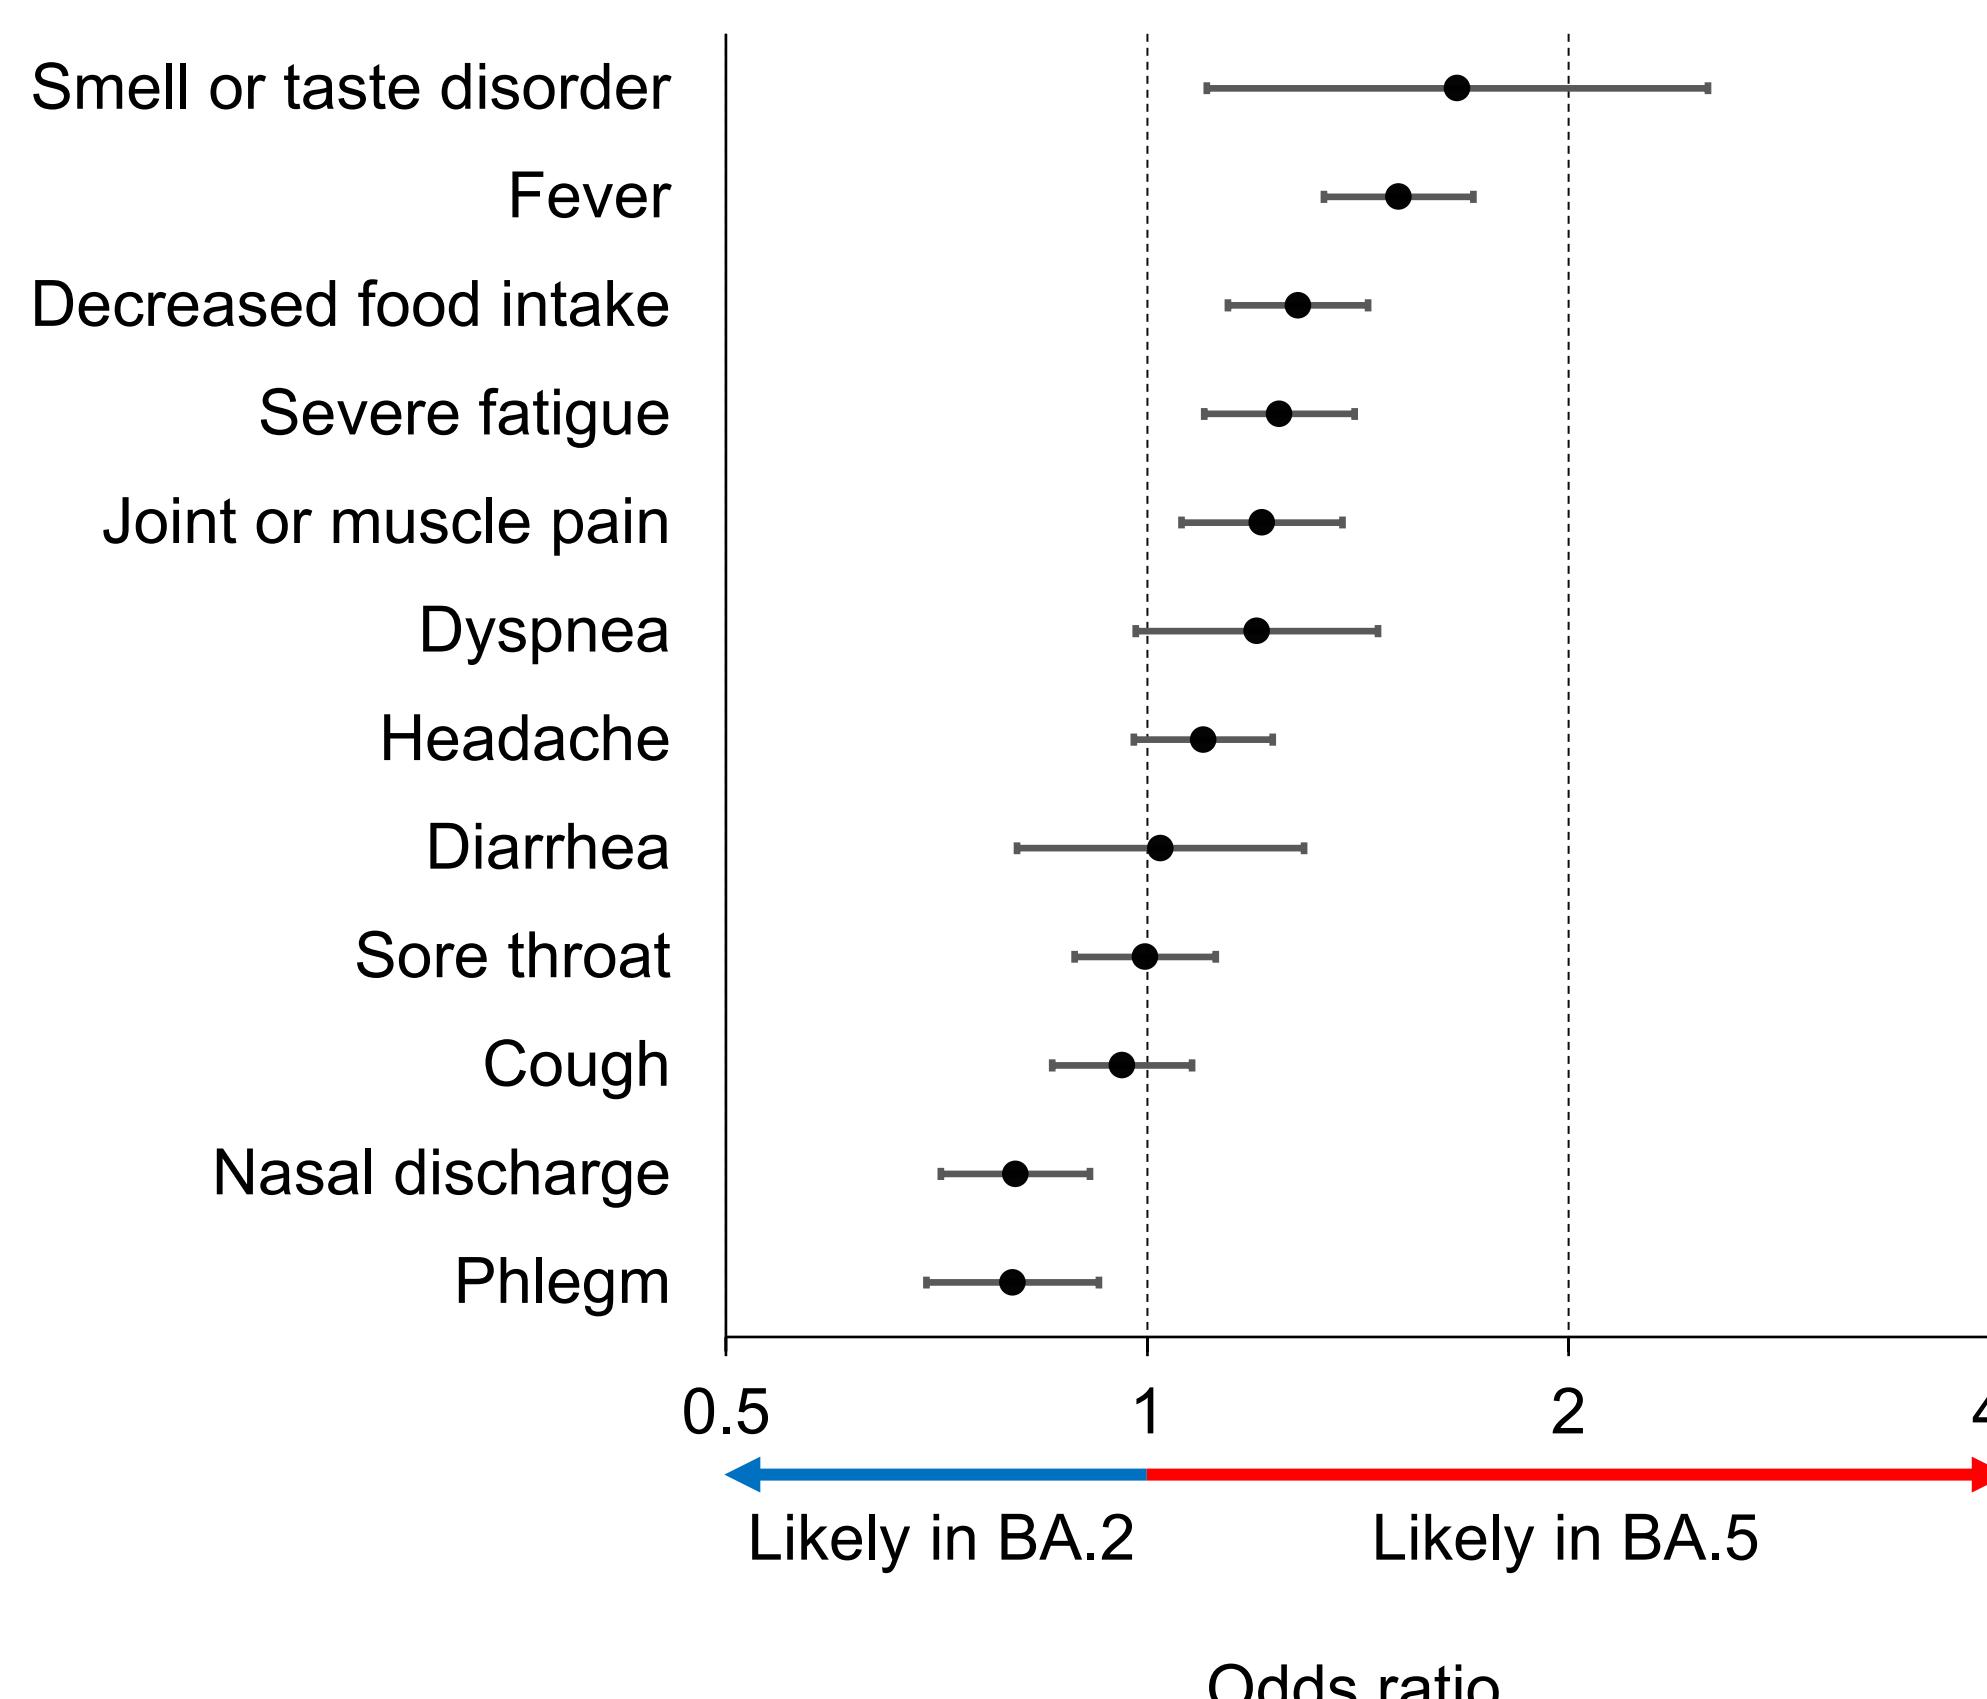

Figure S3. COVID-19 symptom prevalence in unvaccinated individuals. The graph shows the frequencies of 12 symptoms in unvaccinated individuals infected with omicron subvariants BA.2 or BA.5. Error bars indicate 95% confidence intervals.

Figure S4

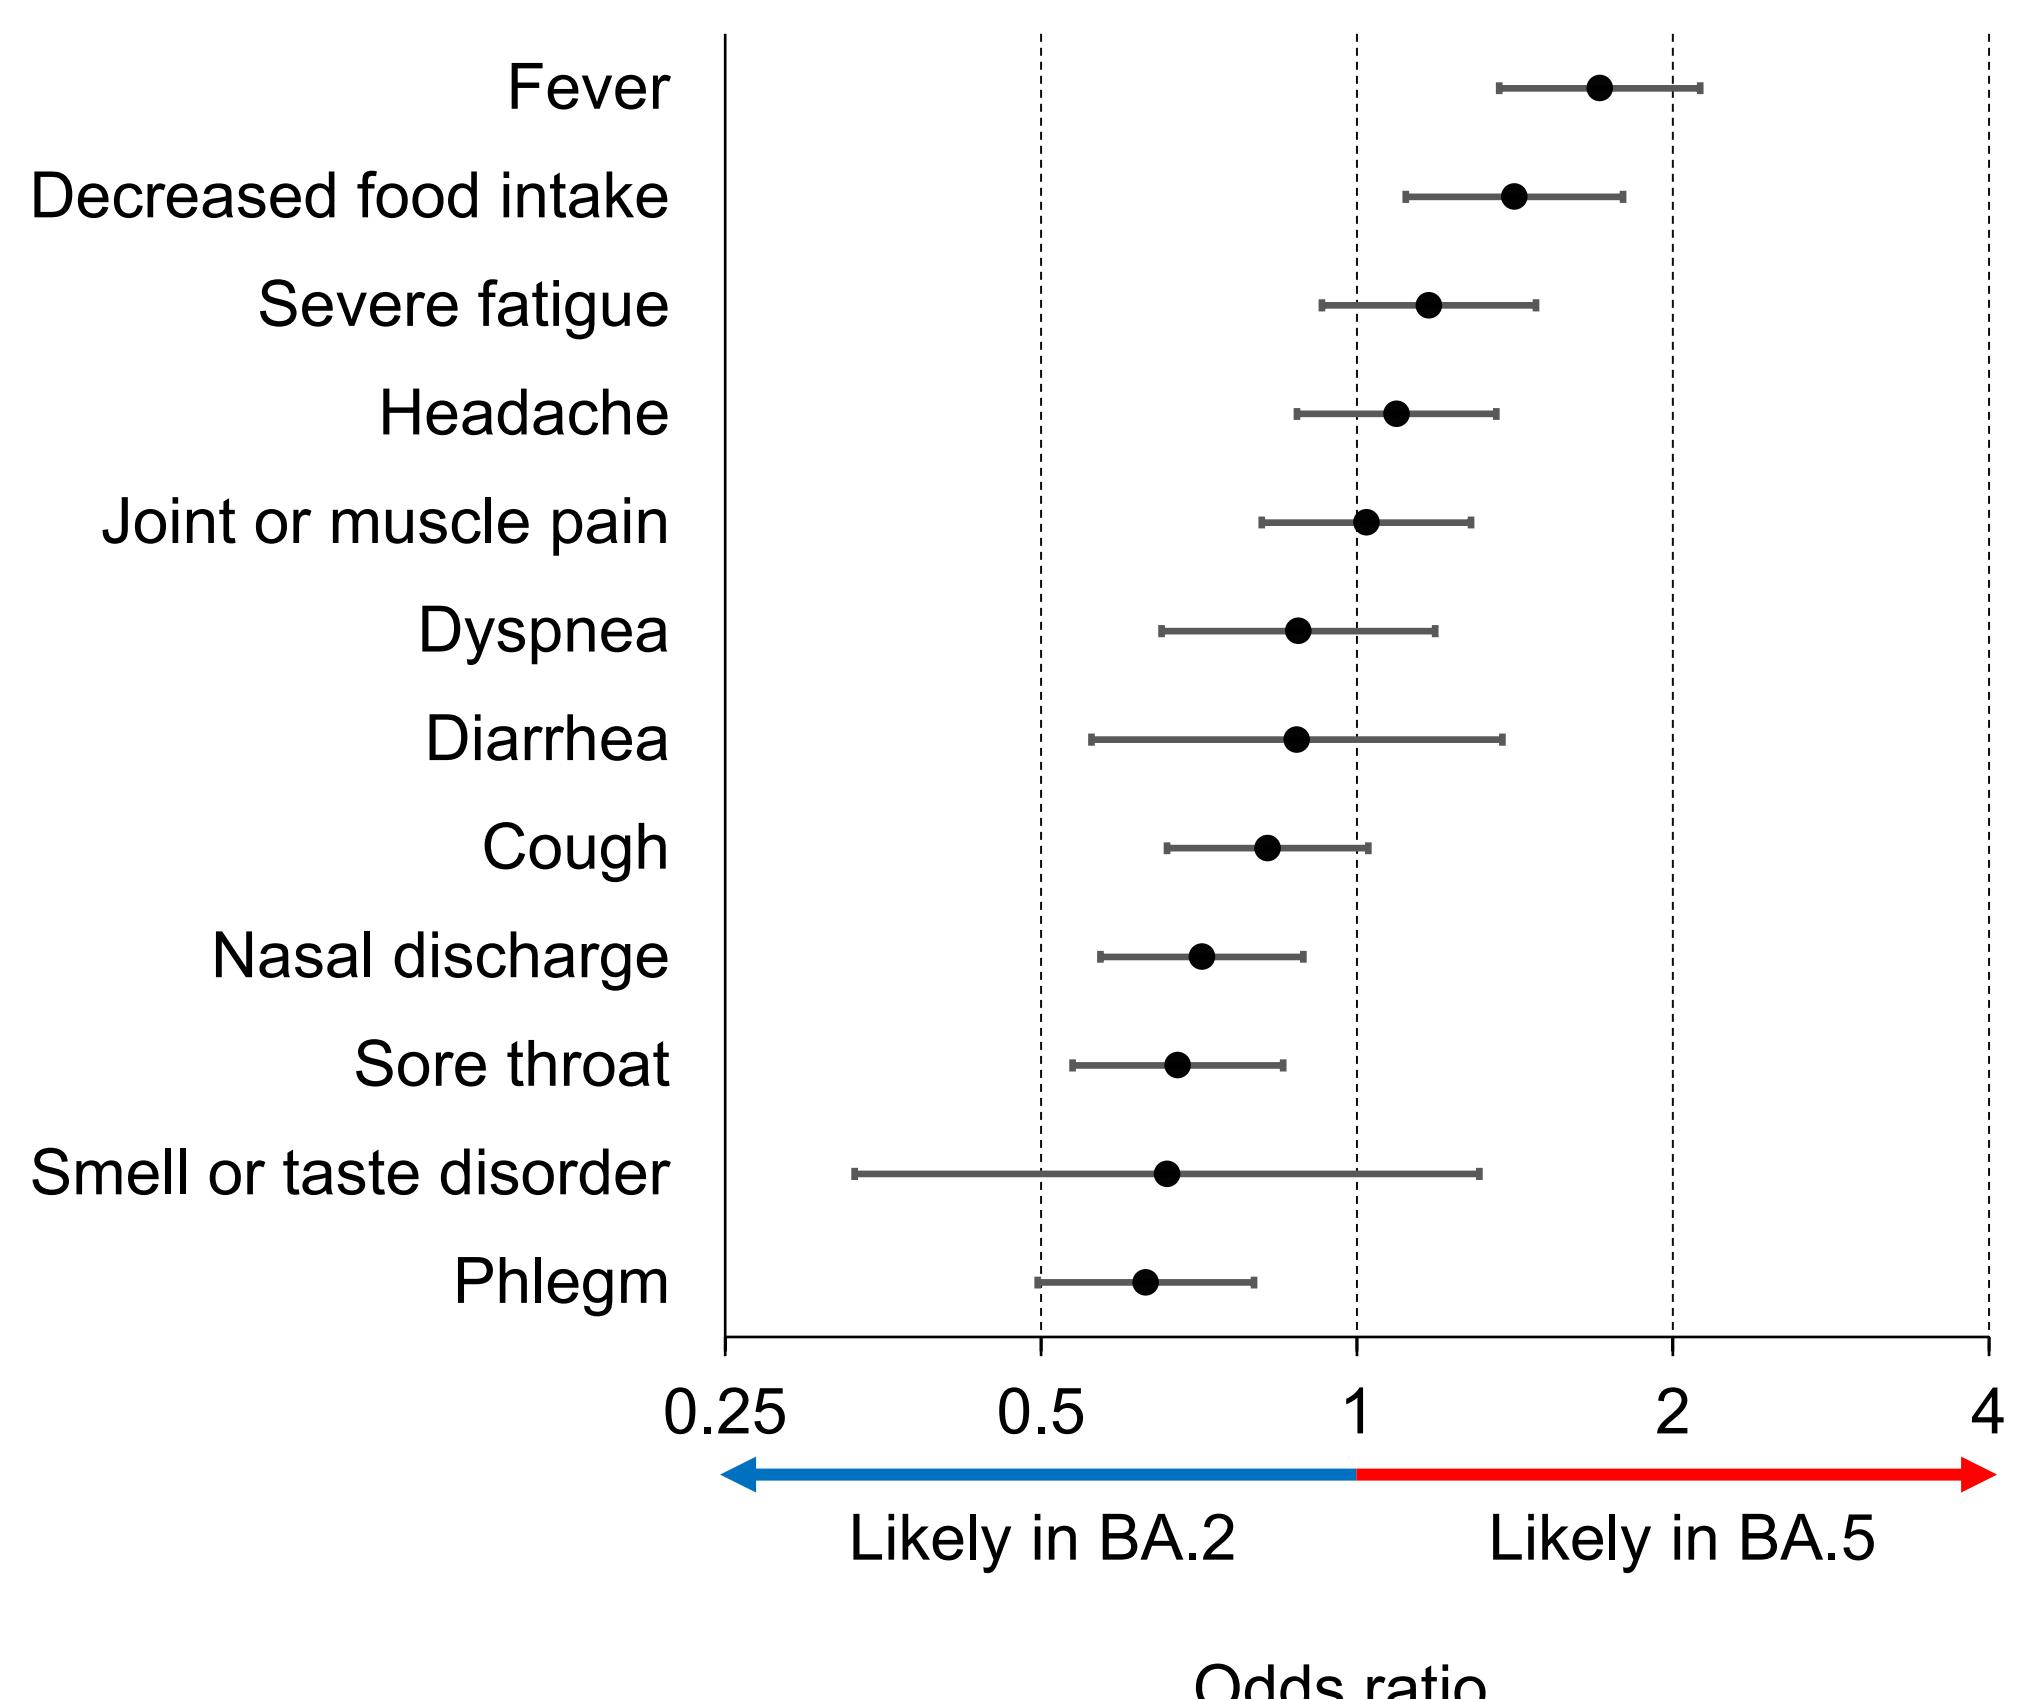

A

Unvaccinated Individuals
1:1 Matched
Symptoms on day of onset

B

2 doses vaccinees
1:1 Matched
Symptoms on day of onset

C

3 doses vaccinees
1:1 Matched
Symptoms on day of onset

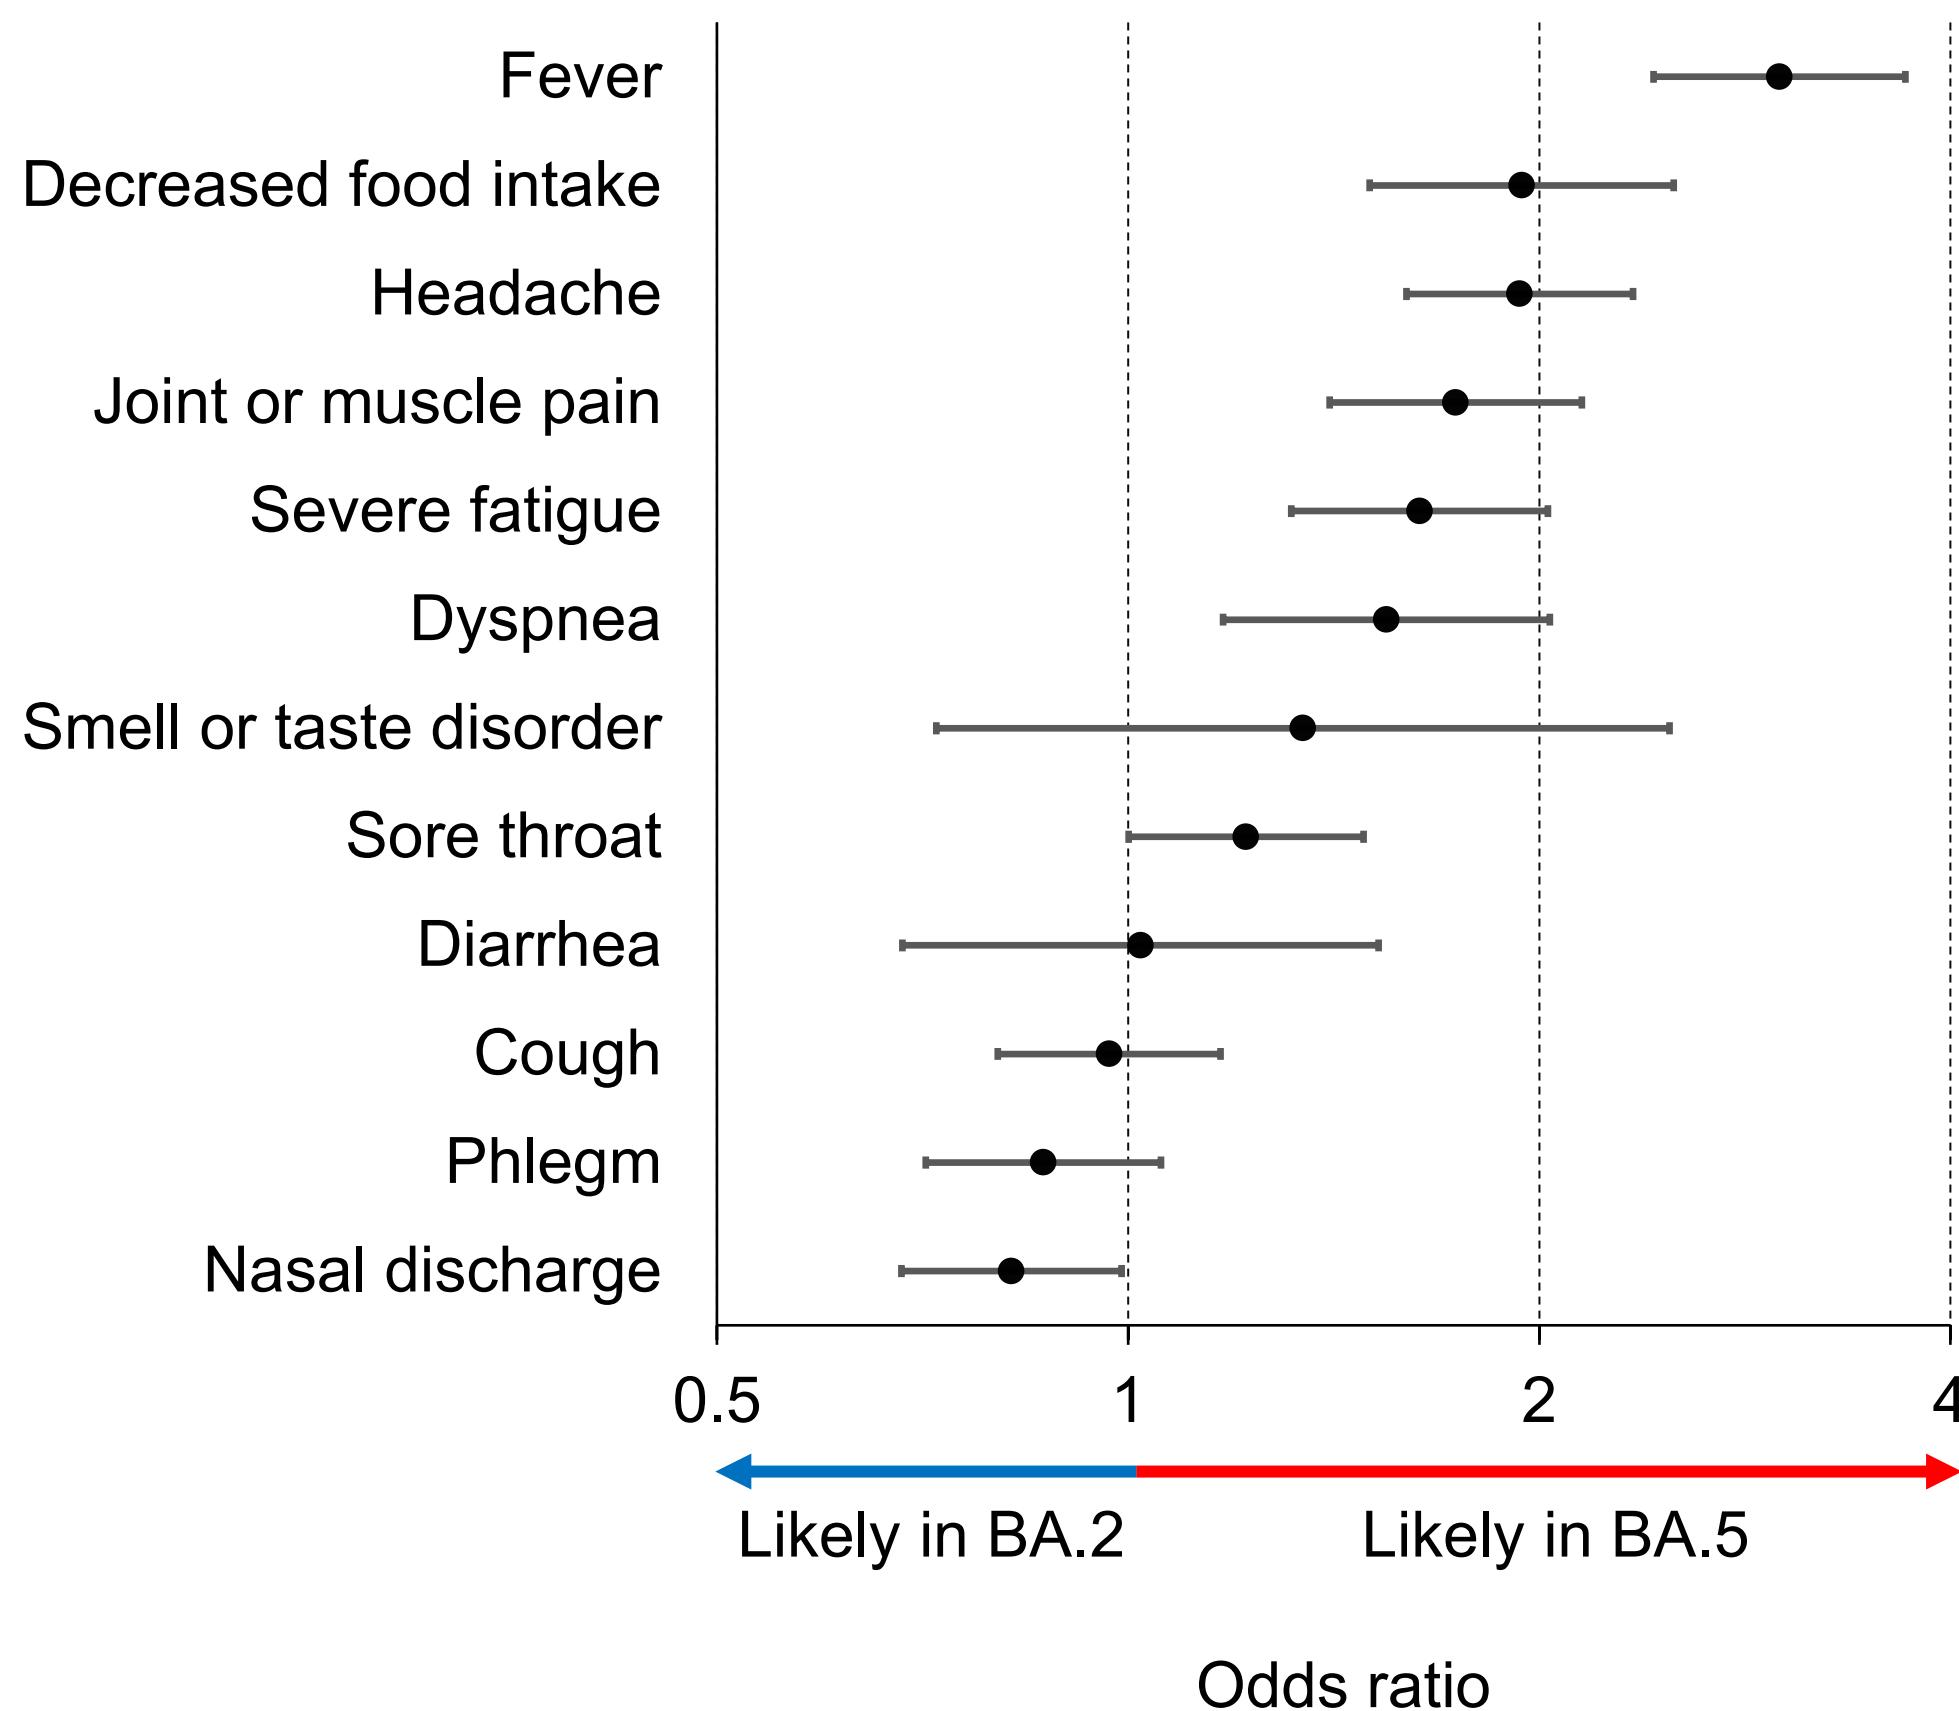

Figure S4. Associations of COVID-19 symptoms with the omicron subvariants BA.2 and BA.5 in subgroups depending on vaccine status. Propensity score 1:1 matching analyses were performed and a propensity score of the type of omicron subvariants was calculated by logistic regression analysis with the variables, including age, sex, obesity, underlying disease, vaccine status, times since last vaccination, and previous SARS-CoV-2 infection. The odds ratios of symptoms for BA.5 to BA.2 are ordered from highest to lowest. The matching was carried out in **A.** unvaccinated, **B.** 2 doses vaccinees and **C.** 3 doses vaccinees. Error bars indicate 95% CI. Detailed results are shown in **Table S6.**

Figure S5

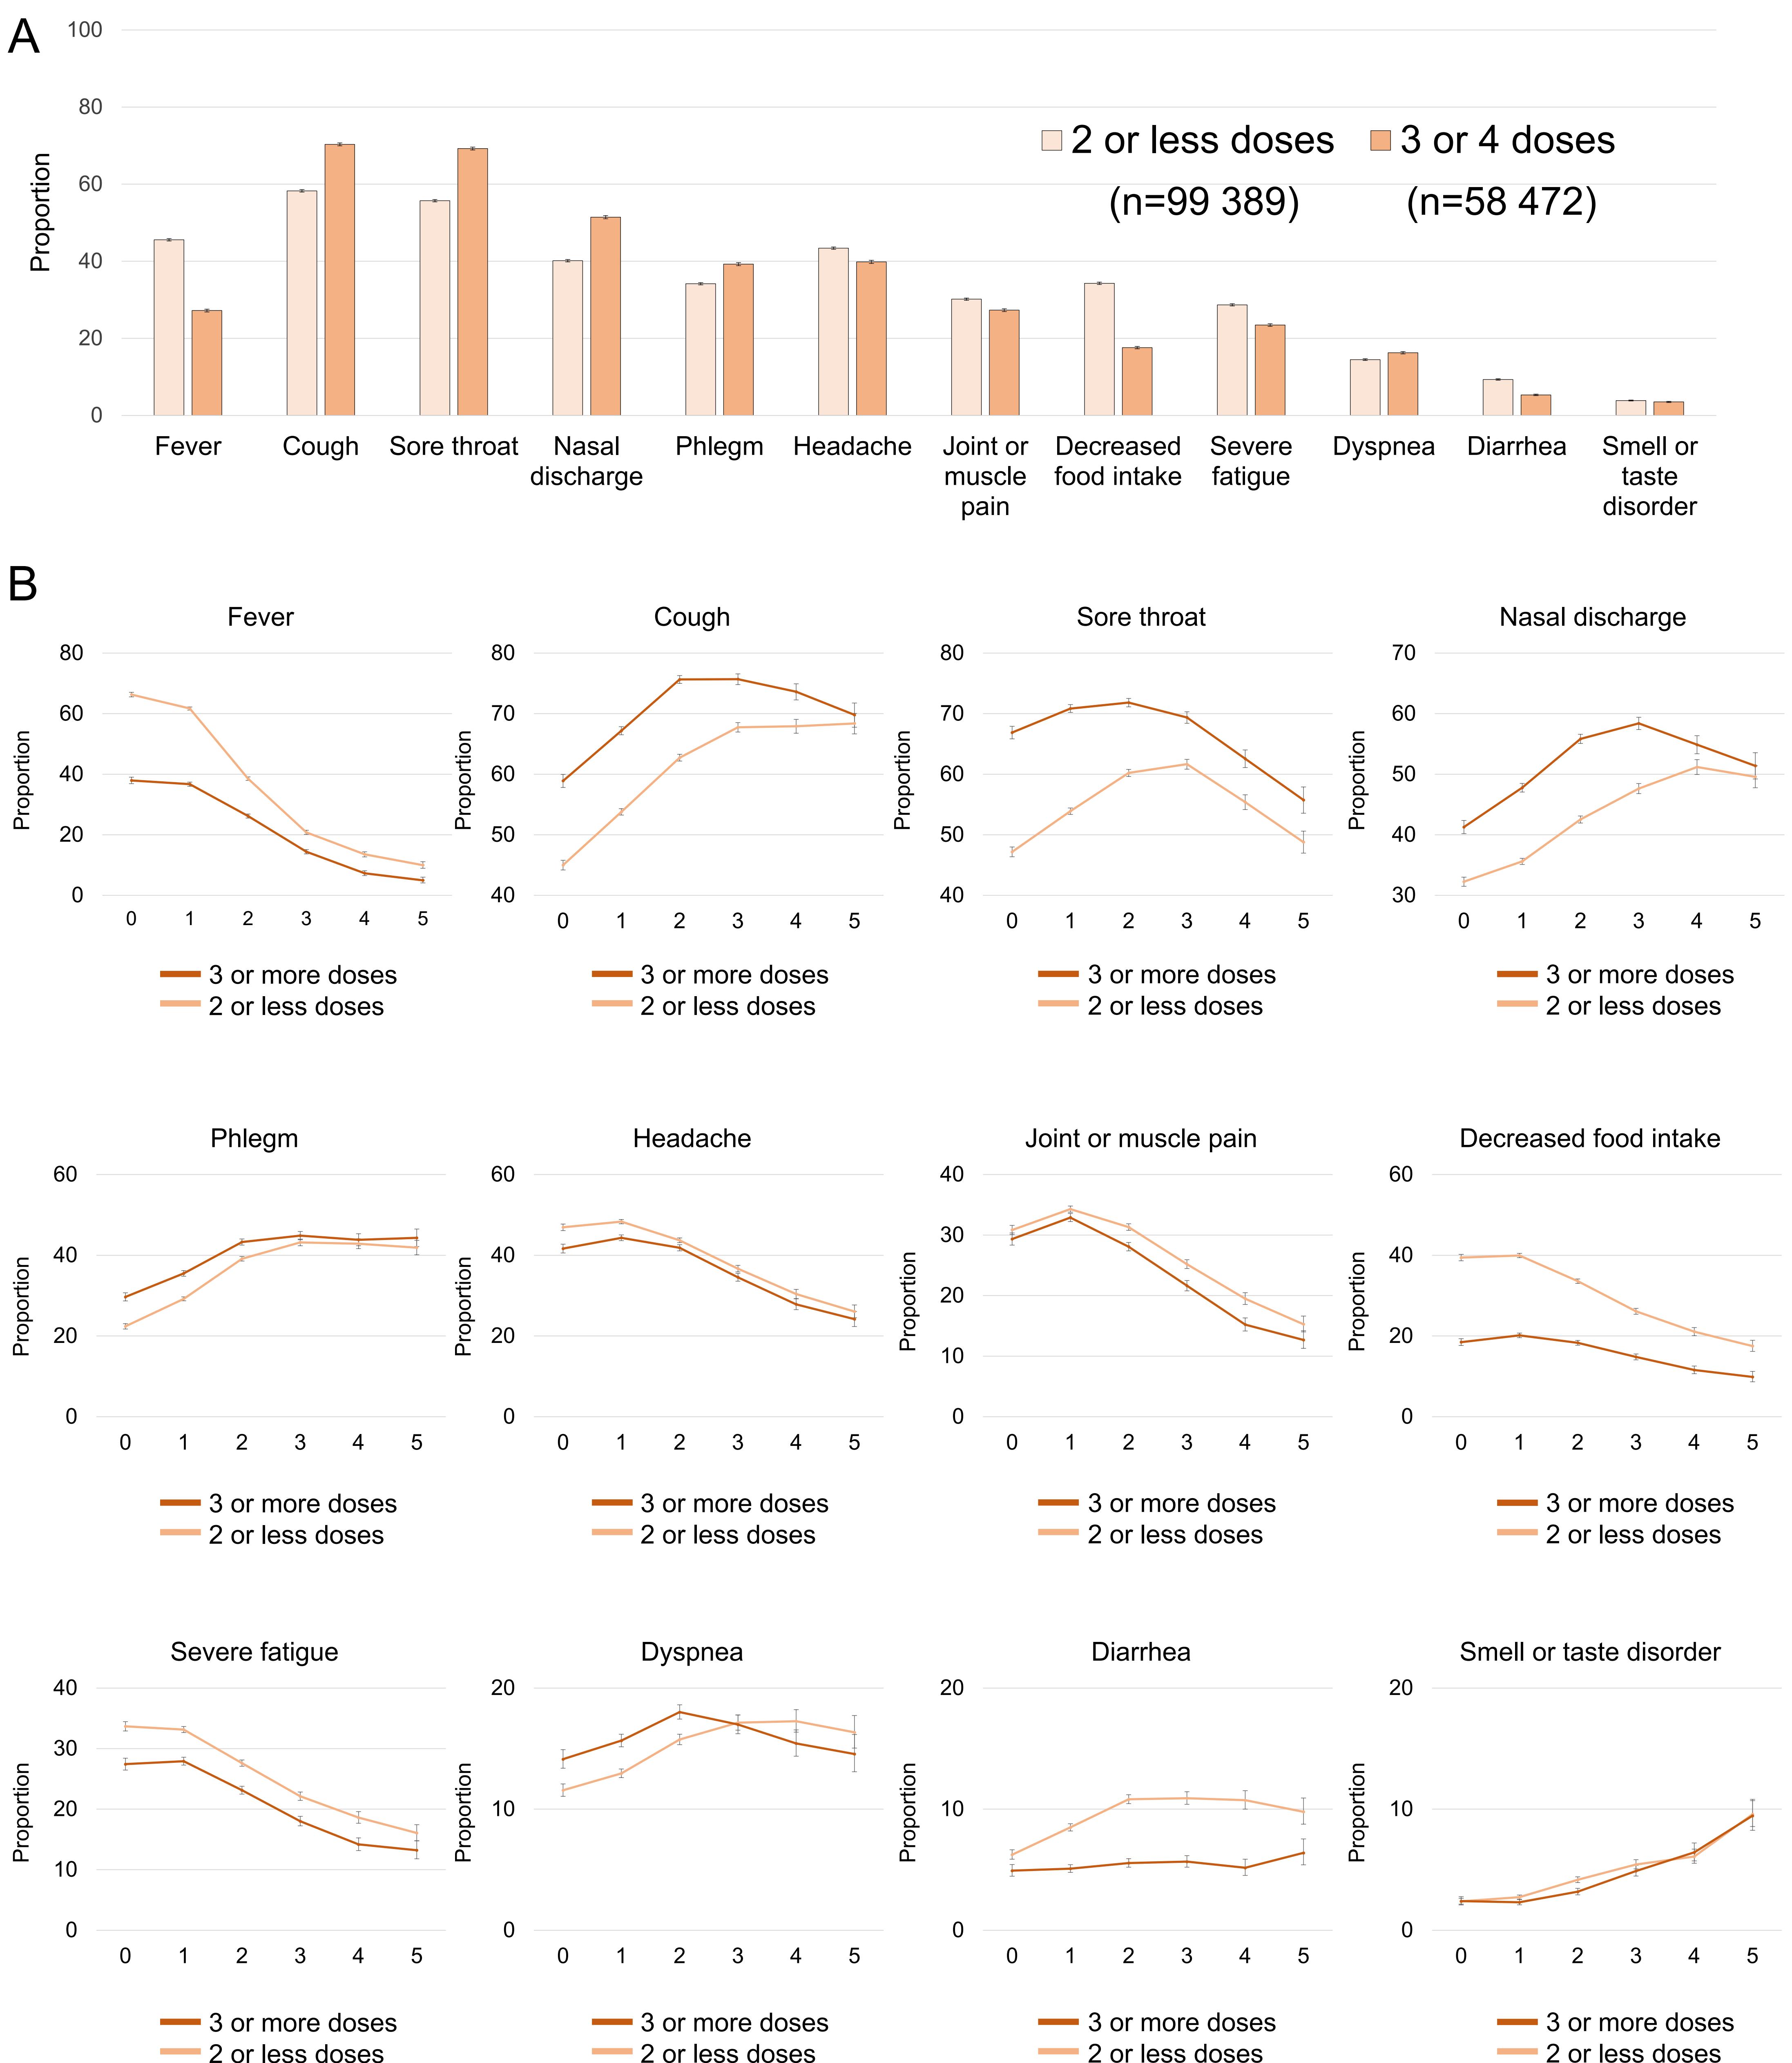

Figure S5. Associations between host vaccine status and COVID-19 symptoms. A. Prevalence of COVID-19 symptoms in individuals with 2 or less doses and 3 or more doses of vaccination. B. Prevalence of COVID-19 symptoms by days since symptom onset. Error bars indicate 95% confidence intervals.

Figure S6
