Supporting Information Placeholder
ABSTRACT: Reductive cyclization of enynes and diynes by using H_2 gas as a reductant was realized, and the corresponding cyclized products were obtained in good yields without olefin-isomerization and over-reduction of the products. By an experiment using D_2 instead of H_2, it was confirmed that H_2 unambiguously operates as a reductant in this reaction. The protocol of the reaction is very economical and user-friendly by using air- and moisture-stable $CoBr_2 \cdot 6H_2O$ and 1 atm pressure of H_2.

Reductive coupling between two different π components (e.g., alkenes, alkynes, and carbonyl groups) is one of the unique reactions catalyzed by transition metal catalysts.[1] Reductive cyclization between diynes or an alkyne and an alkene is a promising methodology for regio- and stereoselective construction of cyclic compounds. Most of the reactions proceed via a metallacycle intermediate formed through oxidative cycloaddition of C-C multiple bonds to a low valent metal complex (M^n), and it is known that various transition metals such as Pd,[2] Ni,[3,4] and Co[3c,5] can catalyze this type of reaction (Scheme 1). As a typical scenario of reductive cyclization of enynes shown in Scheme 1 (a), cleavage of the C-M bond in the metallacycle occurs by a hydrogen source (e.g., HX), giving a cyclized product along with formation of $M^{n+2}X_2$. To establish a catalytic cycle of this reaction, more than a stoichiometric amount of a reductant is necessary to reduce $M^{n+2}X_2$ to M^n. Thus, more than a stoichiometric amount of waste originating from the reductant is also produced after the reaction, and that is a serious drawback of this reaction.

Hydrogen gas (H_2) is one of the ideal reductants in various transformations including the above-mentioned reductive couplings because it is cheap and easily accessible and there is no production of waste after the reaction. Furthermore, with increasing utilization of H_2 in various fields, technology for production of H_2 without CO_2 emission is being developed to replace the traditional methods such as steam reforming.[6] However, the utilization of H_2 as a reductant in transition metal-catalyzed C-C-bond forming reactions has been limited, probably due to competition with catalytic hydrogenation. In 2002, Krische and coworkers reported Rh-catalyzed reductive coupling between an enone and an aldehyde with H_2 (1 atm).[7] After that, they showed that H_2 can be used as a reductant in various types

of reductive coupling, including reductive cyclization of enynes,[8] in a series of their excellent studies.[9] However, reductive cyclizations of enynes or diynes using H_2 as a reductant have been limited, and there have been only a few reports so far.[10] We herein report Co(I)-catalyzed reductive cyclization of enynes and diynes by using 1 atm of H_2 as a reductant (Scheme 1 (b)).[11]

Scheme 1. Transition Metal-Catalyzed Reductive Cyclization of Enynes

(a) A typical scenario of reductive cyclization of enynes

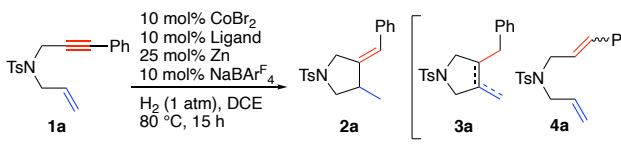

M^n: Ru, Rh, Pd, Ni, Co, etc.
(b) **This work**: Co(I)-catalyzed reductive cyclization of enynes using H_2
Initially, the reaction of enyne **1a** with 10 mol% of the cationic Co(I) catalyst, prepared in situ from $CoBr_2$ (10 mol%) and various ligands in the presence of Zn (25 mol%) and $NaBAr^F_4$ (10 mol%) in a manner similar to the reported procedure,[5a] was carried out in dichloroethane (DCE) at 80 °C under 1 atm of H_2, and the results are

summarized in Table 1. The use of monodentate ligands, PPh$_3$ and PCy$_3$, was not effective for producing the desired compound **2a**, and most of **1a** was recovered in each reaction (Entries 1 and 2). Co(I) catalysts bearing bidentate ligands such as dppe, dppp, dppb, dcpe, and DPEphos promoted the cyclization, but a large amounts of isomerized product **3a** and/or alkyne-reduced starting material **4a** were obtained along with desired product **2a** (Entries 3-7). On the other hand, it was found that Xantphos-type ligands were effective for selective formation of the desired product **2a** without isomerized product **3a**. Thus, reactions of **1a** using Xantphos, N-Xantphos, and Xyl-Xantphos gave **2a** in 68%, 75%, and 83% yields, respectively, with a small amount of the reduced starting material **4a** (Entries 8-10).

Table 1. Ligand Screening in Reaction of 1a^a

| Entry	Ligand	2a (%)	3a (%)	4a (%)	Recov. 1a (%)
1^{b,c}	PPh$_3$	–	–	trace	87
2^d	PCy$_3$	–	–	–	quant.
3	dppe	23	17	5	5
4	dppp	21	44	trace	–
5	dppb	27	46	–	–
6	dcpe	48	33	–	–
7	DPEPhos	17	34	3	–
8	Xantphos	68	–	7	–
9	N-Xantphos	75	–	1	–
10	Xyl-Xantphos	83	–	6	–

^{a}Unless noted otherwise, the yields are isolated ones. ^{b}The yield was determined by ^{1}H-NMR analysis with 1,1,2,2-tetrachloroethane as an internal standard. ^{c}10 mol% of CoBr$_2$(PPh$_3$)$_2$ was used. ^{d}20 mol% of PCy$_3$ was used.
Next, we commenced further optimization of the reaction conditions in the reaction of **1a** using Xyl-Xantphos as a ligand (Table 2). When the reaction temperature was lowered from 80 °C to 60 °C, the yield was not affected, and the cyclized product **2a** was obtained in 82% yield (entry 1). On the other hand, in the reaction at 40 °C, the yield of **2a** was decreased to 52%, and over-reduced product **2a'** was also obtained in 15% yield, although the reason was not clear (Entry 2). For solvents, the reaction in toluene at 60 °C produced **2a** in 76% yield, while the use of THF and CH$_3$CN at the same temperature decreased the yield of **2a** to 36% and 4%, respectively (Entries 3-5). In these reactions, we used a cationic Co(I) catalyst formed in

situ from CoBr$_2$ (10 mol%) and various ligands in the presence of Zn (25 mol%) and NaBAr$^F_4$ (10 mol%). When the amount of Zn was decreased from 2 to 10 mol%, the time required for complete consumption of the substrate **1a** was extended to 39 hours, but **2a** was obtained in good yield (Entry 6). On the other hand, the reaction in the absence of Zn or NaBAr$^F_4$ did not proceed at all, and the starting material **1a** was almost completely recovered (Entries 7 and 8), meaning that these reagents are necessary for formation of the active Co catalyst. It is noteworthy that the reaction under an atmosphere of N$_2$ instead of H$_2$ also did not proceed, indicating that H$_2$ plays a critical role for the reaction to proceed (Entry 9).

Table 2. Optimization for Reductive Cyclization of 1a^a

Entry	conditions	2a (%)	4a (%)	Recov. 1a (%)
1	DCE, 60 °C	82	6	–
2^b	DCE, 40 °C	52	3	–
3	toluene, 60 °C	76	8	–
4	THF, 60 °C	36	59	–
5	CH$_3$CN, 60 °C	4	trace	22
6^c	10 mol% Zn	79	3	–
7^d	w/o Zn	–	–	95
8^d	w/o NaBAr$^F_4$	–	–	98
9^d	w/o H$_2$ (under N$_2$)	–	–	94

^{a}Unless noted otherwise, the yields are isolated ones. ^{b}**2a'** was obtained in 15% yield. ^{c}Reaction time was 39 h. ^{d}The yield was determined by ^{1}H-NMR analysis with 1,1,2,2-tetrachloroethane as an internal standard.
In all of the experiments shown in Tables 1 and 2, commercially available "anhydrous CoBr$_2$" was used as received. Since anhydrous CoBr$_2$ is known to be hygroscopic, we decided to use it after drying by heating at 130 °C *in vacuo* for 24 hours. As a result, in the reaction of **1a** with dried CoBr$_2$ (10 mol%) and Xantphos (10 mol%), the yield of **2a** significantly decreased to 20%, and the starting material **1a** was recovered in 80% yield (Table 3, Entry 1). With the addition of 20 mol% water to the reaction under the same conditions, the yield of **2a** was slightly improved to 36% (Entry 2). Surprisingly, the use of CoBr$_2$·6H$_2$O, which is the most stable hydrate complex of CoBr$_2$, increased the yield of **2a** to 90% (Entry 3). With the use of a Co(I) catalyst under the same conditions with Xyl-Xantphos, the yield of **2a** reached 95% (Entry 4). Furthermore, in the reaction of 1 mmol scale of **1a**, catalyst loading can be reduced to 2 mol%, and the product **2a** was obtained in a high yield (Entry 5). As for the reason why CoBr$_2$·6H$_2$O was more effective than "anhydrous" or dried CoBr$_2$, we speculate that the presence of H$_2$O promoted the reduction of Co(II) species to Co(I) species by zinc. Similarly, Chirik recently reported that the presence of MeOH accelerated the reduction of a Co(II)-diphosphine complex to Co(I)-diphosphine complex by zinc as a reductant.[12]

Table 3. Optimization for Preparation of a Co(I) Catalyst[a]

| Entry	Co(II) complex	2a (%)	4a (%)	Recov. 1a (%)
1[b,c]	CoBr₂ (dried)	20	–	80
2[c]	CoBr₂ (dried)+20 mol% H₂O	36	6	–
3[c]	CoBr₂·6H₂O	90	10	trace
4[d]	CoBr₂·6H₂O	95	4	–
5[e]	2 mol% CoBr₂·6H₂O	85	5	–

[a]Unless noted otherwise, the yields are isolated ones. [b]The yield was determined by ¹H-NMR analysis with 1,1,2,2-tetrachloroethane as an internal standard. [c]Xantphos was used as a ligand. [d]Xyl-Xantphos was used as a ligand. [e]1 mmol of **1a**, Xyl-Xantphos (2 mol%), Zn (5 mol%), and NaBArF₄ (2 mol%) were used in this reaction.

With the optimal conditions in hand, we next investigated the scope of substrates in this cyclization (Table 4). Various substituents, including electron-donating and electron-withdrawing groups, at the *p*-position of the aromatic ring at the terminus of the alkyne of enynes **1** were tolerated to give the corresponding cyclized products **2b**-**2f** in 77%-95% yields. The reaction of **1g** having a methyl group at the *m*-position of the aromatic ring took 24 hours to complete, but the desired product **2g** was obtained in an excellent yield (97%). On the other hand, the reaction of **1h** having a methyl group at the *o*-position did not proceed under the optimal conditions, probably due to the steric repulsion. In this case, however, the use of Xantphos instead of Xyl-Xantphos was effective and the product **2h** was obtained in 91% yield. The existence of a heteroaromatic ring, thiophene, at the terminus of the alkyne somewhat retarded the reaction, but the cyclized product **2i** was obtained in a modest yield (36%). The reaction of **1j** having a methyl group at the terminus of the alkyne gave **2j** in 98% yield, indicating that the existence of an aromatic ring at the alkyne terminus is not essential. The presence of oxygen in the chain is also tolerated, but the yield of **2k** was diminished to 46%. With respect to substrates having longer chains, the reaction of 1,7-enyne **1l** gave the desired product **2l** in 86% yield, while the reaction of 1,8-enyne **1m** did not proceed, recovering **1m** in 87% NMR yield. Next, the reaction of 1,6-diynes were checked under the same conditions. In the case of 1,6-diyne **1n** having a Ts amide moiety and phenyl substituents at each terminus of alkynes, the corresponding product **2n** was obtained in 87% yield. Changing the Ts amide moiety in **1n** to oxygen did not affect the yield of the product, giving **2o** in 70% yield. On the other hand, the malonate derivative **1p** did not seem to be a good substrate in this reaction, giving the corresponding product **2p** in 27% yield. Compared to diynes having phenyl substituents on the alkynes, 1,6-diynes **1q** and **1r** having methyl substituents on the alkynes are not suitable for this reaction, and the corresponding products **2q** and **2r** were obtained in 21% and 11% yields, respectively. Although it is a preliminary result, it is noteworthy that the reaction of allenyne **5** under the optimal conditions gave the product **6** in an excellent yield (99%) (Scheme 2).

Table 4. Scope of Substrates[a]

2b (R'=Me): 95%
2c (R'=Cl): 93%
2d (R'=CF₃): 81%
2e (R'=OMe): 92%
2f (R'=CO₂Me): 77%

2g: 97%[b]

2j: 98%

2k: 46%[f]

2l: 86%

2m: –

2n (X=NTs): 87%
2o (X=O): 70%
2p (X=C(CO₂Me)₂): 27%[g]

2q (X=NTs): 21%[g]
2r (X=C(CO₂Me)₂): 11%[h]

[a]Isolated yields. [b]The reaction time was 24 h. [c]10 mol% of Xantphos was used instead of Xyl-Xantphos. [d]The reaction time was 48 h. [e]The reduced starting material **4i** was also obtained in 27% yield. [f]The residual starting material **1k** was observed as the mixture with unidentified by-products. [g]The starting material was almost consumed, and unidentified byproducts were also formed. [h]Most of the starting material remained but could not be separated from unidentified byproducts.

Scheme 2. Reaction of Allenyne[a]

6: 99%
[a]Isolated yields.

To gain an insight into the reaction mechanism, we conducted the reaction of **1a** under the optimal conditions using deuterium gas (D_2) instead of H_2 (Figure 1, upper part). As a result, the product **2a-d** was obtained in 87% yield, with deuterium being incorporated at each of the expected positions in **2a-d** with high D-contents (>95%). This result indicates that H_2 (or D_2) unambiguously acts as a reductant in the reaction. Also, it means that H_2O in $CoBr_2 \cdot 6H_2O$ and a catalytic amount of Zn (25 mol%) do not operate as reductants for the cyclization, and those would be necessary for preparation of an active Co(I) catalyst from a Co(II) complex.

Figure 1. Reaction using D_2 and Proposed Mechanism

Based on the above-described result, the proposed mechanism of this reductive cyclization is shown in the lower part of Figure 1. A cationic Co(I) catalyst **7** was formed by reduction of $CoBr_2 \cdot 6H_2O$ by Zn in the presence of a ligand and $NaBAr^F_4$. Oxidative addition of substrate **1** to Co(I) catalyst **7** produced cobaltacycle intermediate **I**, which is the common intermediate in reductive cyclization catalyzed by a transition metal catalyst.[1-6] Then, σ-bond metathesis between **I** and H_2 occurred to give intermediate **II**,[13,14] from which reductive elimination afforded product **2** along with regeneration of Co(I) catalyst **7**. We speculate that a Xantphos-type ligand operates as a tridentate ligand in this reaction, which results in the prevention of side reactions such as isomerization and over-reduction by occupation of three coordination sites on the cobalt center.[15]

In conclusion, we succeeded in developing Co(I)-catalyzed reductive cyclization of enynes and diynes using H_2 as a reductant. The remarkable features of this reaction are as follows: (1) The reaction is economical and convenient owing to the use of the base metal Co and easily accessible H_2 and (2) the experimental protocol is user-friendly with easy handling owing to the use of an air-and moisture-stable $CoBr_2 \cdot 6H_2O$ complex under 1 atm pressure of H_2. Further studies including extension to an asymmetric variant are in progress.

(13) We have recently found that $C(sp^2)$-metal bond is more reactive than $C(sp^3)$-metal bond in rhodacyclopentene intermediate, which is a congener of intermediate **I**, toward σ-bond metathesis and insertion of C=X bond. Thus, we speculated that σ-bond metathesis between **I** and H_2 occurred at the $C(sp^2)$-Co bond in **I**. At present, however, other possibilities (e.g., σ-bond metathesis at the $C(sp^3)$-Co bond in **I**, successive insertion of alkyne/alkene to Co-H species generated from Co(I) catalyst and H_2) cannot be excluded. For related references with respect to the reactivity of rhodacyclopentene intermediate, see ref. 14.

For C=O bond insertion, see (e) Oonishi, Y.; Yokoe, T.; Hosotani, A.; Sato, Y. Rhodkum(I)-Catalyzed Cyclization of Allenynes with a Carbonyl Group through Unusual Insertion of a C=O Bond into a Rhodacycle Intermediate. *Angew. Chem. Int. Ed.* **2014**, *53*, 1135-1139. For C=N bond insertion, see (f) Oonishi, Y.; Hato, Y.; Sato, Y. Rhodium(I)-Catalyzed [2+2+2] Cycloaddition between Allene, Alkyne, and Imine via a Strained Azarhodacycle Intermediate. *Adv. Synth. Catal.* **2015**, *357*, 3033-3039. (g) Oonishi, Y.; Hato, Y.; Sato, Y. Rhodium(I)-Catalyzed Diastereoselective Cycloisomerization of Enynes with Tethered (*S*)-2-Methyl-2-propanesulfinyl Imine. *Adv. Synth. Catal.* **2016**, *358*, 2273-2279. (h) Hato, Y.; Oonishi, Y.; Yamamoto, Y.; Nakajima, K.; Sato, Y. Stereoselective Construction of Spiro-Fused Frameworks by Sequential Reaction of Enynes, Imines, and Diazoalkenes with Rh(I) and Rh(III) Catalysts. *J. Org. Chem.* **2016**, *81*, 7847-7854.

(15) It is known that Xantphos-type ligands can operate as tridentate ligands, see: (a) Adams, G. M.; Weller, A. S. POP-Type Ligands: Variable Coordination and Hemilabile Behavior. Coord. Chem. Rev. 2018, 355, 150-172. (b) van Leeuwen, P. W. N. M.; Kamer, P. C. J. Featuring Xantphos. Catal. Sci. Technol. 2018, 8, 26-113.
