SOME NOTES ON THE CHINESE SPECIES OF THE GENUS ACANTHOSOMA CURTIS, 1824
(Hemiptera : Pentatomidae)

By TAMOTSU ISHIHARA

Matsuyama Agricultural College, Matsuyama.

The Genus Acanthosoma CURTIS, 1824 [Brit. Ent., I : 28] is a peculiar genus of Pentatomidae. Although a number of species of the genus were recorded from Asiatic regions, representatives from China have been very poorly known at present.

When I had an opportunity to examine the Chinese specimens of the genus preserved in the Entomological Laboratory, Kyushu University, Fukuoka, I found seven specimens belonging to four species, including an unrecorded and a splendid new species. Now, in this paper, I want to report on the four species with some synonymic notes.

Prior to enter the subject, I express my hearty thanks to Professor TEISO ESAKI whom I am much indebted in many favours.

1. Acanthosoma denticauda JAKOVLEV, 1880

1880 Acanthosoma Kiritschenkoi LINDBERG, Ark. f. Zool., Bd. 27 A (23): 11, Tat. 1; Fig. 2 (♀, Tienshian) syn. nov.?

Specimen examined: 1 ♀, Foochow, Fukien, 5. VIII. 1935, E. SÜENSON leg.

Distribution: Amur, Corea, China (hab. nov.: Fukien, Sinchang), Japan (Hokkaido, Honshu, Shikoku, Kyushu).

This is one of the commonest species of the genus in Japan, but was unrecorded from China till now. JENSEN-HAARUP, 1931 [Deutsch. Ent. Zeitschr., Jahrg. 1930, IV : 218] established a new subspecies japonica from Japan with the following description: "somewhat larger than typical specimens, but especially remarkable by the prominent and subacute humeral angles of pronotum," but these characters are individually very variable, so I do not agree with him. Acanthosoma Kiritschenkoi LINDBERG,
1934 [loc. cit., Fig. 2.] which was described from Tienshan, Sinchiang, basing upon a single female specimen may be also probably a variant of the present species.

2. **Acanthosoma labiduroides** Jakovlev, 1880

1926 *Acanthosoma labiduroides* Esaki, Ann. Mus. Nat. Hang., XXXIII: 198, Pl. 4, Fig. 17–19 (China, etc.).

Specimen examined: 1♀, S. Shensi, 12. VI. 1936, E. Suenson leg.

Distribution: Amur, Corea, China (S. Shensi), Japan (Hokkaido, Honshu, Shikoku, Kyushu).

This species is fairly common in the mountainous regions of Japan, but no one has reported this species from China since the first record from there by T. Esaki, 1926 [loc. cit.], in which only "China" was added to its distribution.

3. **Acanthosoma spinicolle** Jakovlev, 1880

1939 *Acanthosoma axillarum* Jakovlev, Horae Soc. Ent. Rossicae, XXIII: 52 (♀♂, Irkutsk) syn. nov.?

1926 *Acanthosoma spinocolle* Esaki, loc. cit., 198, Pl. 4; Fig. 1–3 (Kuldsha, etc.).

1931 *Acanthosoma Potamini* Lindberg, loc. cit., 10, Taf. 1; Fig. 1 (♀, Kansu, Szechwan) syn. nov.

---

**Fig. 1. Acanthosoma axillarum** sp. nov.

A ♀. B ♂.
1935 Acanthosoma spinicolis Hoffmann, loc. cit., 102 (Kulja, etc.).
Distribution: Aigur, Irkutsk, China (Sinchang, Kansu, Szechwan, Shansi), Japan (Hokkaido, Honshu).

Apices of humeral angles of this species are not always so spinous as to the specific name may suggest. One of the specimens reported here has dull angles and is destitute of the black tint at their extreme apices. Judging by the description and the figure, Acanthosoma Potanini Lindberg, 1934 [loc. cit.], which was described from Kansu and Szechwan, and Acanthosoma axillare Jakovlev, 1889 [loc. cit.] which was known from Irkutsk (Type-locality) and Tienshan, Sinchiang [Lindberg, 1934, loc. cit., p. 10] seem to be also variants of the present species.

Thus:

Humeral angles red with black spinous apices [typical form] ..............................................
........................ A. spinicolle Jakovlev, 1880
Humeral angles red with black dull apices [variant form?] ..............................................
........................ A. axillare Jakovlev, 1889
Humeral angles totally red, dull [variant form] ... A. Potanini Lindberg, 1934

4. Acanthosoma ouchii sp. nov.
Head light brown, with fairly strong lustre and blackly punctures, which are scarce on clypeus and coarse on lateral lobes. Eyes black. Ocelli reddish-brown. Of antennae, the basal two segments greenish-yellow, the third with the basal half greenish-yellow, the apical half dark brown and pubescent, the apical two segments dark brown and pubescent. Rostrum brown, with black apex. Pronotum generally brown, slightly tinted with green in the middle and darkened posteriorly, with apical angles levigate, light brown and with humeral angles levigate, hardly punctate, freshly sanguineous in hue. Scutellum greenish-brown, shining, with coars: black punctures. Membrane light brownish, semitransparent. Legs light brown, levigate, with conspicuous whitish setae on tibiae, especially near apex, and on tarsi. Claws
light brown except each apex which is black. Body beneath mostly light brown, with pale spiracles. Genital styles brownish red and its neighbouring abdominal segment tinted with brownish red. Parameres brown except black apex.

Body comparatively oblong. Head shorter than width including eyes (about 11:16), anteriorly convergent and subtruncated apically (clypeus very slightly protruding lateral lobes), with rostrum reaching middle coxae. Eyes fairly large, projecting laterally. Of antennae, first segment thick, a little curving outward, equal to the fifth segment in length, second slightly longer than the first, third shortest, fourth the longest. Pronotum wider than the width of head including eyes at the anterior margin, apical angles conspicuous, subacute, projecting anteriorly, humeral angles very well developed, projecting antero-laterally and a little curving posteriorly towards apex which is subacute. Mesosternal lamina anteriorly projecting beyond the anterior margin of mesosternum. Scutellum almost equi-lateral, slightly longer than the width (about 13:11), at the anterior margin which is anteriorly convex. Hemielytra comparatively long, distinctly protruding the apices of genital styles. Spine of the first abdominal segment hardly reaching the anterior coxae. Genital segments as shown in the figure.

♀. Body larger, antennae shorter than in the male.
Length of body including hemielytra: 15.2 mm., ♀ 16.3 mm.
Width of body including humeral angles: 10.1 mm., ♀ 11.2 mm.
Length of each antennal segment: I : II : III : IV : V, ♀ 2.00 : 2.25 : 1.67 : 2.33 : 2.00 mm., ♀ 1.79 : 1.92 : 1.42 : 2.17 : 1.79 mm.
Habitat: China (Tienmu-shan).
Holotype ♀, Tienmu-shan, Chekiang, China, 8. VII. 1936, YOSHI OUCHI leg., Allotopotype ♀, 9. VII. 1936, YOSHI OUCHI leg.

Although the present new species is allied to Acanthosoma angulatum JAKOYLEV, 1880, from Amur, Saghalien and Japan (Hokkaido, Honshu, Shikoku, Kyushu), it may be easily distinguished by the large conspicuous sanguineous humeral angles. The specific name is dedicated to the collector.
